Introduction

Created: June 23, 2008; Updated: January 7, 2021.

Sequence similarity searching is one of the more important bioinformatics activities and often provides the first evidence for the function of a newly sequenced gene or piece of sequence. Basic Local Alignment Search Tool (BLAST) is probably the most popular similarity search tool. The National Center for Biotechnology Information (NCBI) first introduced BLAST in 1989. The NCBI has continued to maintain and update BLAST since the first version. In 2009, the NCBI introduced a new version of the stand-alone BLAST applications (BLAST+). The BLAST+ applications have a number of improvements that allow faster searches as well as more flexibility in output formats and in the search input. These improvements include: splitting of longer queries so as to reduce the memory usage and to take advantage of modern CPU architectures; use of a database index to dramatically speed up the search; the ability to save a “search strategy” that can be used later to start a new search; and greater flexibility in the formatting of tabular results.

The functionality of the BLAST+ applications is organized by search type. As an example, there is a “blastp” application that compares proteins queries to protein databases. The “blastx” application translates a nucleotide query in six frames and searches it against a protein database. This organization is different from that of the applications first released in 1997 (e.g., blastall) that supported all types of searches with one application, but it resembles that of the NCBI BLAST web site. An advantage of this design is that each application has only the options relevant to the searches it performs. Additionally, each application can compare a query to a set of FASTA sequences in a file, bypassing the need to create a BLAST database for small and infrequently searched sets. Finally, a “remote” option permits each application to send off a search to the NCBI servers.

This manual has several sections. It provides brief installation instructions, a QuickStart, a section describing BLAST+ features in more depth, a “Cook Book” section on how to perform a number of tasks, as well as three appendices. The first appendix discusses tools to help with the transition from the older applications (e.g., blastall) to the BLAST+ applications. The second appendix documents exit codes from the BLAST+ applications. The third appendix is a table of BLAST options, the type of input required, and the default values for each application. The fourth appendix lists the scoring parameters that the blastn application supports.

An introduction to BLAST is outside the scope of this manual, more information on this subject can be found on http://blast.ncbi.nlm.nih.gov/Blast.cgi?CMD=Web&PAGE_TYPE=BlastDocs.

Please feel free to contact us with any questions, feedback, or bug reports at blast-help@ncbi.nlm.nih.gov.

Installation

Created: June 23, 2008; Updated: January 7, 2021.

Installation instructions are available for [Windows](#) and [LINUX/UNIX](#). This section provides instructions for a few cases not covered by those entries.

The BLAST+ applications are distributed both as an executable and as source code. For the executable formats we provide installers as well as tarballs; the source code is only provided as a tarball. These are freely available at <ftp://ftp.ncbi.nlm.nih.gov/blast/executables/blast+/>. Please be sure to use the most recent available version; this will be indicated in the file name (for instance, in the sections below, version 2.2.18 is listed, but this should be replaced accordingly).

MacOSX

For users without administrator privileges: follow the procedure described in <http://www.ncbi.nlm.nih.gov/books/NBK52640/>

For users with administrator privileges and machines MacOSX version 10.5 or higher: Download the ncbi-blast-2.2.18+.dmg installer and double click on it. Double click the newly mounted ncbi-blast-2.2.18+ volume, double click on ncbi-blast-2.2.18+.pkg and follow the instructions in the installer. By default the BLAST+ applications are installed in /usr/local/ncbi/blast, overwriting its previous contents (an uninstaller is provided and it is recommended when upgrading a BLAST+ installation).

RedHat Linux

Download the appropriate *.rpm file for your platform and either install or upgrade the ncbi-blast+ package as appropriate using the commands:

```
Install:
    rpm -ivh ncbi-blast-2.2.18-1.x86_64.rpm
Upgrade:
    rpm -Uvh ncbi-blast-2.2.18-1.x86_64.rpm
```

Note: one must have root privileges to run these commands. If you do not have root privileges, please use the procedure described in <http://www.ncbi.nlm.nih.gov/books/NBK52640/>

Source tarball

Use this approach to build the BLAST+ applications yourself. Download the tarball, expand it, change directories to the newly created directory, and type the following commands:

```
cd c++
./configure
cd ReleaseMT/build
make all_r
```

The compiled executables will be found in c++/ReleaseMT/bin. Please note that this sequence of commands will build the applications with optimizations, with support for multi-threading and it may require the installation of dependencies (see following section). If a different configuration is desired, please use the configure.orig script located in the same directory.

Building sources in Windows

Extract the appropriate tarball (e.g.: `ncbi-blast-VERSION+-x64-win64-tar.gz`) and open the appropriate MSVC solution or project file (e.g.: `c++\compilers\msvc1000_prj\static\build\ncbi_cpp.sln`), build the `-CONFIGURE-` project, click on “Reload” when prompted by the development environment, and then build the `-BUILD-ALL-` project. The compiled executables will be found in the directory corresponding to the build configuration selected (e.g.: `c++\compilers\msvc1000_prj\static\bin\debugdll`).

Note regarding building the source code

The BLAST source tarballs are a subset of the NCBI C++ toolkit. Information on using and compiling the NCBI C++ toolkit is available at <http://www.ncbi.nlm.nih.gov/toolkit/doc/book>. Please send questions about compiling the NCBI C++ toolkit to toolbox@ncbi.nlm.nih.gov

Dependencies

Created: June 23, 2008; Updated: January 7, 2021.

Run-time

- For `get_species_taxids.sh`
 - E-Direct: <https://dataguide.nlm.nih.gov/edirect/install.html>
- For `update_blastdb.pl`
 - Perl: <https://www.perl.org/>
- For Windows only:
 - Visual Studio 2015 C++ redistributable runtime package: <https://www.microsoft.com/en-us/download/details.aspx?id=48145>

Compile time

- **LMDB** library (starting with BLAST+ 2.7.1): needed if you are compiling BLAST from source code.

Quick start

Created: June 23, 2008; Updated: January 7, 2021.

A BLAST search against a database requires at least a `-query` and `-db` option. The command:

```
blastn -db nt -query nt.fsa -out results.out
```

will run a search of `nt.fsa` (a nucleotide sequence in FASTA format) against the `nt` database, printing results to the file `results.out`. If “`-out results.out`” had been left off, the results would have been printed to stdout (i.e., the screen). **The `blastn` application searches a nucleotide query against a nucleotide database.**

To send the search to our servers and databases, add the `-remote` option:

```
blastn -db nt -query nt.fsa -out results.out -remote
```

See more about this option in the section below, BLAST+ remote service.

The BLAST+ applications print documentation when invoked with the `-h` or `-help` option. The `-h` option provides abbreviated help, and the `-help` flag provides more extensive documentation. For example, use `-help` to get a list of output options for the `-outfmt` option.

Create a custom database from a multi-FASTA file of sequences with this minimal command:

```
makeblastdb -in mydb.fsa -dbtype nucl -parse_seqids
```

See the section below, Building a BLAST database with local sequences, for more details.

The BLAST databases are required to run BLAST locally and to support automatic resolution of sequence identifiers. Documentation about these identifiers can be found at http://www.ncbi.nlm.nih.gov/toolkit/doc/book/ch_demo/#ch_demo.T5. The databases may be retrieved automatically with the `update_blastdb.pl` PERL script, which is included as part of this distribution. This script will download multiple tar files for each BLAST database volume if necessary, without having to designate each volume. For example:

```
./update_blastdb.pl --decompress swissprot
```

will download all the relevant swissprot tar files.

The script can also compare your local copy of the database tar file(s) and only download tar files if the date stamp has changed reflecting a newer version of the database. This will allow the script run on a schedule and only download tar files when needed. Documentation for the `update_blastdb.pl` script can be obtained by running the script without any arguments (perl is required).

RPS-BLAST ready databases are available at <ftp://ftp.ncbi.nih.gov/pub/mmdb/cdd/>

The BLAST taxonomy database is required in order to print the scientific name, common name, blast name, or super kingdom as part of the BLAST report or in a report with `blastdbcmd`. The BLAST database contains only the taxid (an integer) for each entry, and the taxonomy database allow BLAST to retrieve the scientific name etc. from a taxid. The BLAST taxonomy database consists of a pair of files (`taxdb.bti` and `taxdb.btd`) that are available as a compressed archive from the NCBI BLAST FTP site (<ftp://ftp.ncbi.nlm.nih.gov/blast/db/taxdb.tar.gz>). The `update_blastdb.pl` script can be used to download and update this archive; it is recommended that the uncompressed contents of the archive be installed in the same directory where the BLAST databases reside. Assuming proper file permissions and that the BLASTDB environment variable contains the path to the installation directory of the BLAST databases, the following commands accomplish that:

```
# Download the taxdb archive
perl update_blastdb.pl taxdb
```

```
# Install it in the BLASTDB directory
gunzip -cd taxdb.tar.gz | (cd $BLASTDB; tar xvf - )
```

Privacy

Created: June 23, 2008; Updated: January 7, 2021.

Privacy Statement

The BLAST+ executables are command-line tools that you run on non-NCBI computers. No information about your search is sent over the network, unless you explicitly elect to. This offers you greater privacy control than using web tools or the `-remote` option on a BLAST+ executable.

For quality monitoring, the BLAST+ executables, starting with the 2.11.0 release, send some information about usage statistics back to NCBI. This information is limited to the name of the BLAST executable (e.g., `blastp`), database metadata, a few BLAST parameters, as well the number and total size of your queries without any data association that might reveal the context of your research. No sequences from your queries or database are sent to the NCBI. An example list is below.

These reports help us improve BLAST as well as measure our impact on the community, which in turn justifies funds to support and further develop BLAST, so please report your usage.

Opt-out of Usage Reporting

You can opt-out of the usage reporting by adding a `.ncbirc` (UNIX like) or `ncbi.ini` (Windows) configuration file. In the configuration file you should add a line under the BLAST section to set `BLAST_USAGE_REPORT` to `false`. See [here](#) for details on setting up a configuration file.

You may also opt-out of the usage reporting by setting the environment variable `BLAST_USAGE_REPORT` to `false`. In bash (under LINUX) this command would look like:

```
export BLAST_USAGE_REPORT=false
```

Note that this environment variable is only set in the shell (i.e. window) you are currently using and will not be set the next time you login. To permanently opt-out, this variable should be set every time a new shell is opened or with a configuration file, as described above.

You can also set this environment variable, turning off usage reporting, when using BLAST+ docker by adding the `-e` option to your docker invocation:

```
-e BLAST_USAGE_REPORT=false
```

Below is the information that would be reported for a BLASTP search

```
IP=27.18.28.18
comp_based_stats=2
db_date=Aug 26, 2020 3:12 AM
db_length=179658219
db_name=swissprot
db_num_seqs=474714
evaluate_threshold=10.000000
exit_status=0
hitlist_size=500
ncbi_app=standalone-blast
ncbi_location=be-md
ncbi_role=production

Functionality offered by BLAST+ applications

Tom Madden¹

Created: June 23, 2008; Updated: September 25, 2020.

The functionality offered by the BLAST+ applications has been organized by program type, as to more closely resemble Web BLAST.

As an example, to run a search of a nucleotide query (translated “on the fly” by BLAST) against a protein database one would use the blastx application. The blastx application will also work in “Blast2Sequences” mode (i.e.: accept FASTA sequences instead of a BLAST database as targets) and can also send BLAST searches over the network to the public NCBI server if desired.

The BLAST+ package offers three categories of applications: 1.) search tools, 2.) BLAST database tools, and 3.) sequence filtering tools. The blastn, blastp, blastx, tblastx, tblastn, psiblast, rpsblast, and rpstblastn are considered search applications, as they execute a BLAST search, whereas makeblastdb, blastdb_aliastool, makeprofiledb, and blastdbcmd are considered BLAST database applications, as they either create or examine BLAST databases.

There is also a new set of sequence filtering applications described in the section Sequence filtering applications and an application to build database indices that greatly speed up megablast in some cases (see section titled Megablast indexed searches).

BLAST+ features

Tom Madden¹

Created: June 23, 2008; Updated: September 25, 2020.

Tasks

The blastn and blastp applications have a `-task` option. This option sets the parameters (e.g., word-size or gap values) to typical values for a specific type of search. For example, the “megablast” task is optimized for intraspecies comparison as it uses a large word-size, whereas “blastn” is better suited for interspecies comparisons with a shorter word-size. These tasks resemble the “Program Selection” section of the BLAST web pages and do not preclude the user from setting other options to override those specified by the task. See Appendix "Options for the command-line application" for documentation on parameter values for different tasks. The following tasks are currently available:

Program	Task Name	Description
blastp	blastp	Traditional BLASTP to compare a protein query to a protein database
	blastp-short	BLASTP optimized for queries shorter than 30 residues
blastn	blastn	Traditional BLASTN requiring an exact match of 11
	blastn-short	BLASTN program optimized for sequences shorter than 50 bases
	megablast	Traditional megablast used to find very similar (e.g., intraspecies or closely related species) sequences
	dc-megablast	Discontiguous megablast used to find more distant (e.g., interspecies) sequences

Megablast indexed searches

Indexing provides an alternative way to search for initial matches in nucleotide-nucleotide searches (blastn and megablast) by pre-indexing the N-mer locations in a special data structure, called a database index.

Using an index can improve search times significantly under certain conditions. It is most beneficial when the queries are much shorter than the database and works best for queries under 1 Mbases long. The advantage comes from the fact that the whole database does not have to be scanned during the search.

Indices can capture masking information, thereby enabling search against databases masked for repeats, low complexity, etc.

There are, however, limitations to using indexed search in blast:

- Index files are about four times larger than the blast databases. If an index does not fit into computer operating memory, then the advantage of using it is eliminated.

- Word size must be set to 16 or more in order to use an indexed search.
- Discontiguous search is not supported.

Reference: Morgulis A, Coulouris G, Raytselis Y, Madden TL, Agarwala R, Schäffer AA. Database Indexing for Production MegaBLAST Searches. *Bioinformatics* 2008, 24(16):1757-64. [PMID:18567917](#)

BLAST search strategies

BLAST search strategies are files that encode the inputs necessary to perform a BLAST search. The purpose of these files is to be able to seamlessly reproduce a BLAST search in various environments (Web BLAST, command line applications, etc).

Exporting search strategies on the Web BLAST

Click on "download" next to the RID/saved strategy in the "Recent Results" or "Saved Strategies" tabs.

Exporting search strategies with BLAST+ applications

Add the `-export_search_strategy` along with a file name to the command line options.

Importing search strategies on Web BLAST

Go to the "Saved Strategies" tab, click on "Browse" to select your search strategy file, then click on "View" to load it into the submission page.

Importing search strategies with BLAST+ applications

Add the `-import_search_strategy` along with a file name containing the search strategy file. Note that if provided, the `-query`, `-db`, `-use_index`, and `-index_name` command line options will override the specifications of the search strategy file provided (no other command line options will override the contents of the search strategy file).

Negative GI lists

Search applications support negative GI lists. This feature provides a means to exclude GIs from a BLAST database search. The expect values in the BLAST results are based upon the sequences actually searched and not on the underlying database. For an example, see the cookbook.

Masking in BLAST databases

It is now possible to create BLAST databases that contain filtered sequences (also known as masking information or masks). This filtering information can be used for soft or hard masking of the subject sequences. For instructions on creating masked BLAST databases, please see the cookbook.

Custom output formats for BLAST searches

The BLAST+ search command line applications support custom output formats for the tabular and comma-separated value output formats. For more details see "outfmt" in Appendix "Options for the command-line application" as well as the cookbook.

Custom output formats to extract BLAST database data

blastdbcmd supports custom output formats to extract data from BLAST databases via the `-outfmt` command line option. For more details see the blastdbcmd options in Appendix “Options for the command-line application” as well as the cookbook.

Improved software installation packages

The BLAST+ applications are available via Windows and MacOSX installers as well as RPMs (source and binary) and unix tarballs. For more details about these, refer to the installation section.

Sequence filtering applications

The BLAST+ applications include a new set of sequence filtering applications, namely segmasker, dustmasker, and windowmasker. Segmasker is an application that identifies and masks low complexity regions of protein sequences. The dustmasker application provides a similar functionality for nucleotide sequences.

Windowmasker uses a genome to identify sequences represented too often to be of interest to most users. See <ftp://ftp.ncbi.nlm.nih.gov/pub/agarwala/dustmasker/README.dustmasker> and <ftp://ftp.ncbi.nlm.nih.gov/pub/agarwala/windowmasker/README.windowmasker> for more information.

Best-Hits filtering algorithm

The Best-Hit filtering algorithm is designed for use in applications that are searching for only the best matches for each query region reporting matches. Its `-best_hit_overhang` parameter, *H*, controls when an HSP is considered short enough to be filtered due to presence of another HSP. For each HSP *A* that is filtered, there exists another HSP *B* such that the query region of HSP *A* extends each end of the query region of HSP *B* by at most *H* times the length of the query region for *B*.

Additional requirements that must also be met in order to filter *A* on account of *B* are:

- i. $\text{evaluate}(A) \geq \text{evaluate}(B)$
- ii. $\text{score}(A)/\text{length}(A) < (1.0 - \text{score_edge}) * \text{score}(B)/\text{length}(B)$

We consider 0.1 to 0.25 to be an acceptable range for the `-best_hit_overhang` parameter and 0.05 to 0.25 to be an acceptable range for the `-best_hit_score_edge` parameter. Increasing the value of the overhang parameter eliminates a higher number of matches, but increases the running time; increasing the `score_edge` parameter removes smaller number of hits.

Automatic resolution of sequence identifiers

The BLAST+ search applications support automatic resolution of query and subject sequence identifiers specified as GIs or accessions (see the cookbook section for an example). This feature enables the user to specify one or more sequence identifiers (GIs and/or accessions, one per line) in a file as the input to the `-query` and `-subject` command line options.

Upon encountering this type of input, by default the BLAST+ search applications will try to resolve these sequence identifiers in locally available BLAST databases first, then in the BLAST databases at NCBI, and finally in Genbank (the latter two data sources require a properly configured internet connection). These data sources can be configured via the `DATA_LOADERS` configuration option and the BLAST databases to search can be configured via the `BLASTDB_PROT_DATA_LOADER` and `BLASTDB_NUCL_DATA_LOADER` configuration options (see the section on Configuring BLAST).

BLAST-WindowMasker integration in BLAST+ search applications

The BLAST+ search applications support integration with the windowmasker files via the -window_masker_taxid and the WINDOW_MASKER_PATH configuration parameter (see Configuring BLAST) or via the -window_masker_db command line option.

In the first case, the WINDOW_MASKER_PATH configuration parameter should refer to a directory which contains subdirectories named after NCBI taxonomy IDs (e.g.: 9606 for human, 10090 for mouse), where the windowmasker unit counts data files should be placed with the following naming convention: wmasker.obinary (for files generated with the obinary format) and/or wmasker.oascii (for files generated with the oascii format). For an example on how to create these files, please see the Cookbook. Once these windowmasker files and the configuration file are in place, this feature can be invoked by providing the taxonomy ID to the -window_masker_taxid command line option.

Alternatively, this feature can also be invoked by providing the path to the windowmasker unit counts data file via the -window_masker_db.

Please see the Cookbook for a usage example of this feature.

DELTA-BLAST: A tool for sensitive protein sequence search

DELTA-BLAST uses RPS-BLAST to search for conserved domains matching to a query, constructs a PSSM from the sequences associated with the matching domains, and searches a sequence database. Its sensitivity is comparable to PSI-BLAST and does not require several iterations of searches against a large sequence database. See the cookbook for more information.

Concatenation of queries

BLAST works more efficiently if it scans the database once for multiple queries. This feature is known as concatenation. It speeds up MegaBLAST searches the most as they spend little time on tasks that consume CPU and most of the time streaming through the database. BLASTN and discontinuous MegaBLAST searches also run faster with concatenation, though the effect is less pronounced. BLAST+ applies concatenation on all types of searches (e.g., also BLASTP, etc.), and it can be very beneficial if the input is a large number of queries in FASTA format. BLAST+ concatenates queries by grouping them together until a specific number of letters (or “chunk size”) is reached. Unfortunately, a constant chunk size for each database scan causes certain problems. For some searches the chunk size is too large, too many letters are searched at once, and the process consumes too much memory. Tests have shown that the number of successful ungapped extensions performed in the preliminary stage is a good predictor of overall memory use during a search. The BLASTN application (starting with the 2.2.28 release) takes advantage of this insight to provide an “adaptive chunk size”. The application starts with a low initial chunk size of 10,000 bases and records how many successful ungapped extensions were performed during search. It adjusts the chunk size on the next database scan with a target of performing two million extensions during the search.

Query concatenation also means that BLAST will produce no output until the first set of concatenated queries have been processed. Some users find this disconcerting, but it is not a problem.

BLAST+ remote service

The BLAST+ applications can also send a search to the servers at the NCBI. In this case, the BLAST+ application is acting as a client and there is no need to install a database or provide more than minimal computing power. The BLAST+ remote service uses the same servers used by the NCBI BLAST website. The BLAST server can

return a Request ID (RID) as part of the results, and that RID can be used to reformat the results with the `blast_formatter` or on the NCBI website. In general, the servers keep the results for an RID for 36 hours. The BLAST+ applications will use the remote service if the `-remote` flag is added to the command line. The BLAST+ remote service uses a shared resource (the computers at the NCBI), so only one BLAST+ application should run remote searches at a time. An example in the cookbook section demonstrates a remote search.

Configuring BLAST

Tom Madden¹

Created: June 23, 2008; Updated: September 25, 2020.

The BLAST+ search applications can be configured by means of a configuration file or environment variables.

Configuring BLAST via configuration file

This can be accomplished with a configuration file named `.ncbirc` (on Unix-like platforms) or `ncbi.ini` (on Windows). This is a plain text file that contains sections and key-value pairs to specify configuration parameters. Lines starting with a semi-colon are considered comments. The application will search for the file in the following order and locations:

1. Current working directory (*)
2. User's HOME directory (*)
3. Directory specified by the NCBI environment variable
4. The standard system directory (“/etc” on Unix-like systems, and given by the environment variable `SYSTEMROOT` on Windows)

(*) Unless the `NCBI_DONT_USE_LOCAL_CONFIG` environment variable is defined.

The search for this file will stop at the first location where it is found and the configurations settings from that file will be applied. If the configuration file is not found or if the `NCBI_DONT_USE_NCBIRC` environment variable is defined, the default values will apply. The following are the possible configuration parameters that impact the BLAST+ applications:

Configuration Parameter	Specifies	Default value
BLASTDB	Path to BLAST databases.	Current working directory
DATA_LOADERS	Data loaders to use for automatic sequence identifier resolution. This is a comma separated list of the following keywords: <code>blastdb</code> , <code>genbank</code> , and <code>none</code> . The <code>none</code> keyword disables this feature and takes precedence over any other keywords specified.	<code>blastdb,genbank</code>
BLASTDB_PROT_DATA_LOADER	Locally available BLAST database name to search when resolving protein sequences using BLAST databases. Ignored if <code>DATA_LOADERS</code> does not include the <code>blastdb</code> keyword.	<code>nr</code>
BLASTDB_NUCL_DATA_LOADER	Locally available BLAST database name to search when resolving nucleotide sequences using BLAST databases. Ignored if <code>DATA_LOADERS</code> does not include the <code>blastdb</code> keyword.	<code>nt</code>
BLAST_USAGE_REPORT	Specifies whether or not usage information should be returned to the NCBI. Set this value to <code>false</code> to disable this feature.	<code>true</code>

Table continued from previous page.

GENE_INFO_PATH	Path to gene information files (NCBI only).	Current working directory
WINDOW_MASKER_PATH	Path to windowmasker directory hierarchy.	Current working directory

The following is an example with comments describing the available parameters for configuration:

```
; Start the section for BLAST configuration
[BLAST]

Configuring BLAST via environment variables

Please note that the environment variables take precedence over any settings from the NCBI configuration file.

Environment Variable	Specifies
NCBI	Path to NCBI configuration file.
NCBI_DONT_USE_NCBI_RC	If defined, no NCBI configuration file will be used.
NCBI_DONT_USE_LOCAL_CONFIG	If defined, no NCBI configuration file on the local directory or the user's HOME directory will be used
BLASTDB	Path to BLAST databases.
BLASTMAT	Path to scoring matrix files.
BATCH_SIZE	See “Controlling concatenation of queries” and “Memory usage” sections below.
NCBI_CONFIG__BLAST__X	Assuming X is any of the configuration parameters from the previous section, it serves the same purpose.

Table continued from previous page.

BLAST_USAGE_REPORT	Specifies whether or not usage information should be returned to the NCBI. Set this variable to false to disable this feature.
--------------------	--

Controlling concatenation of queries

As described above, BLAST+ works more efficiently if it scans the database once for multiple queries. This feature is known as concatenation. Unfortunately, for some searches the concatenation values are not optimal, too many queries are searched at once, and the process can consume too much memory. For applications besides BLASTN (which uses an adaptive approach), it is possible to control these values by setting the BATCH_SIZE environment variable. Setting the value too low will degrade performance dramatically, so this environment variable should be used with caution.

Memory usage

The BLAST search programs can exhaust all memory on a machine if the input is too large or if there are too many hits to the BLAST database. If this is the case, please see your operating system documentation to limit the memory used by a program (e.g.: ulimit on Unix-like platforms). Setting the BATCH_SIZE environment variable as described above may help.

Input formats to BLAST

Tom Madden¹

Created: June 23, 2008; Updated: September 25, 2020.

Multiple sequence alignment

The `-in_msa` psiblast option provides a way to jump start psiblast from a master-slave multiple sequence alignment computed outside psiblast. The multiple sequence alignment must contain the query sequence as one of its sequences, but it need not be the first sequence. The multiple sequence alignment must be specified in a format that is derived from Clustal, but without some headers and trailers (see example below).

The rules are also described by the following words. Suppose the multiple sequence alignment has N sequences. It may be presented in one or more blocks, where each block presents a range of columns from the multiple sequence alignment. E.g., the first block might have columns 1-60, the second block might have columns 61-95, the third block might have columns 96-128. Each block should have N rows, one row per sequence. The sequences should be in the same order in every block. Blocks are separated by one or more blank lines. Within a block there are no blank lines, and each line consists of one sequence identifier followed by some whitespace followed by characters (and gaps) for that sequence in the multiple sequence alignment. In each column, all letters must be in upper case, or all letters must be in lower case.

```

Cookbook

Created: June 23, 2008; Updated: January 7, 2021.

Get NCBI BLAST databases

Created: June 23, 2008; Updated: January 7, 2021.

The best way to obtain BLAST databases is to download them from NCBI or cloud providers (currently from Google Cloud Platform and Amazon Web Services). These are the same databases available via the public BLAST Web Service (<https://blast.ncbi.nlm.nih.gov>), are updated regularly, and contain taxonomic information built into them. These can also be a source of biological sequence data (see below).

To download a preformatted NCBI BLAST database, run the `update_blastdb.pl` program followed by any relevant options and the name(s) of the BLAST databases to download. For example:

```
$ update_blastdb.pl --decompress nr [*]
```

This command will download the compressed nr BLAST database *from NCBI* to the current working directory and decompress it. **Any subsequent identical invocations of this script with the same parameters in that directory will only download any data if it has a different time stamp when compared to the data at NCBI.**

The `update_blastdb.pl` script can determine if you are calling it from within a cloud provider and will automatically download from the appropriate cloud bucket.

If you would like to see what BLAST databases are available to download, please run:

```
$ update_blastdb.pl --showall [*]
```

For more information on available NCBI BLAST databases, please see <https://go.usa.gov/xPhky> . For a demo of this tool, please see <https://bit.ly/2UA7tYb> (external link).

For more details about what command line options this tool supports, please run:

```
$ update_blastdb.pl --help
```

If you need FASTA from these BLAST databases, you can obtain it as follows:

```
$ blastdbcmd -entry all -db nr -out nr.fsa
```

If you need FASTA for selected sequence(s) from these BLAST databases, you can obtain it as follows (the sequence of interest is identified by the accession u00001 in this example):

```
$ blastdbcmd -entry u00001 -db nr -out u00001.fsa
```

[*] If you run into any problems with this invocation, please try the `-passive` option, which is enabled by default in BLAST+ 2.8.1 and following. The `--decompress` option is only needed if the source data comes from NCBI

Create a masked BLAST database

Created: June 23, 2008; Updated: January 7, 2021.

Creating a masked BLAST database is a two step process:

- a. Generate the masking data using a sequence filtering utility like windowmasker or dustmasker
- b. Generate the actual BLAST database using makeblastdb

For both steps, the input file can be a text file containing sequences in FASTA format, or an existing BLAST database created using makeblastdb. We will provide examples for both scenarios.

Collect mask information files

For nucleotide sequence data in FASTA files or BLAST database format, we can generate the mask information files using windowmasker or dustmasker. Windowmasker masks the over-represented sequence data and it can also mask the low complexity sequence data using the built-in dust algorithm (through the -dust option). To mask low-complexity sequences only, we will need to use dustmasker.

For protein sequence data in FASTA files or BLAST database format, we need to use segmasker to generate the mask information file.

The following examples assume that BLAST databases, listed in “Obtaining sample data for this cookbook entry”, are available in the current working directory. Note that you should use the sequence id parsing consistently. In all our examples, we enable this function by including the “-parse_seqids” in the command line arguments.

Create masking information using dustmasker

We can generate the masking information with dustmasker using a single command line:

```
$ dustmasker -in hs_chr -infmt blastdb -parse_seqids \
  -outfmt maskinfo_asn1_bin -out hs_chr_dust.asnb
```

Here we specify the input is a BLAST database named hs_chr (-in hs_chr -infmt blastdb), enable the sequence id parsing (-parse_seqids), request the mask data in binary asn.1 format (-outfmt maskinfo_asn1_bin), and name the output file as hs_chr_dust.asnb (-out hs_chr_dust.asnb).

If the input format is the original FASTA file, hs_chr.fa, we need to change input to -in and -infmt options as follows:

```
$ dustmasker -in hs_chr.fa -infmt fasta -parse_seqids \
  -outfmt maskinfo_asn1_bin -out hs_chr_dust.asnb
```

Create masking information using windowmasker

To generate the masking information using windowmasker from the BLAST database hs_chr, we first need to generate a counts file:

```
$ windowmasker -in hs_chr -infmt blastdb -mk_counts \
  -parse_seqids -out hs_chr_mask.counts
```

Here we specify the input BLAST database (-in hs_chr -infmt blastdb), request it to generate the counts (-mk_counts) with sequence id parsing (-parse_seqids), and save the output to a file named hs_chr_mask.counts (-out hs_chr_mask.counts).

To use the FASTA file hs_chr.fa to generate the counts, we need to change the input file name and format:

```
$ windowmasker -in hs_chr.fa -infmt fasta -mk_counts \
  -parse_seqids -out hs_chr_mask.counts
```

With the counts file we can then proceed to create the file containing the masking information as follows:

```
$ windowmasker -in hs_chr -infmt blastdb -ustat hs_chr_mask.count \
  -outfmt maskinfo_asn1_bin -parse_seqids -out hs_chr_mask.asnb
```

Here we need to use the same input (-in hs_chr -infmt blastdb) and the output of step 1 (-ustat hs_chr_mask.counts). We set the mask file format to binary asn.1 (-outfmt maskinfo_asn1_bin), enable the sequence ids parsing (-parse_seqids), and save the masking data to hs_chr_mask.asnb (-out hs_chr_mask.asnb).

To use the FASTA file hs_chr.fa, we change the input file name and file type:

```
$ windowmasker -in hs_chr.fa -infmt fasta -ustat hs_chr.counts \
  -outfmt maskinfo_asn1_bin -parse_seqids -out hs_chr_mask.asnb
```

Create masking information using segmasker

We can generate the masking information with segmasker using a single command line:

```
$ segmasker -in refseq_protein -infmt blastdb -parse_seqids \
  -outfmt maskinfo_asn1_bin -out refseq_seg.asnb
```

Here we specify the refseq_protein BLAST database (-in refseq_protein -infmt blastdb), enable sequence ids parsing (-parse_seqids), request the mask data in binary asn.1 format (-outfmt maskinfo_asn1_bin), and name the out file as refseq_seg.asnb (-out refseq_seg.asnb).

If the input format is the FASTA file, we need to change the command line to specify the input format:

```
$ segmasker -in refseq_protein.fa -infmt fasta -parse_seqids \
  -outfmt maskinfo_asn1_bin -out refseq_seg.asnb
```

Extract masking information from FASTA sequences with lowercase masking

We can also extract the masking information from a FASTA sequence file with lowercase masking (generated by various means) using convert2blastmask utility. An example command line follows:

```
$ convert2blastmask -in hs_chr.mfa -parse_seqids -masking_algorithm repeat \
  -masking_options "repeatmasker, default" -outfmt maskinfo_asn1_bin \
  -out hs_chr_mfa.asnb
```

Here the input is hs_chr.mfa (-in hs_chr.mfa), enable parsing of sequence ids, specify the masking algorithm name (-masking_algorithm repeat) and its parameter (-masking_options “repeatmasker, default”), and ask for asn.1 output (-outfmt maskinfo_asn1_bin) to be saved in specified file (-out hs_chr_mfa.asnb).

Create BLAST database with the masking information

Using the masking information data files generated in the previous 4 steps, we can create BLAST database with masking information incorporated.

Notes:

1. we should use “-parse_seqids” in a consistent manner – either use it in both steps or not use it at all.
2. Starting with the 2.10.0 release, makeblastdb produces version 5 databases by default, which uses LMDB. LMDB requires virtual memory (at least 600 GB, but 800 GB is recommended). Virtual memory is just

that (virtual) and doesn't depend on the hardware in your system. In general, we recommend that BLAST users simply set the virtual memory to unlimited.

Create BLAST database with masking information using an existing BLAST database or FASTA sequence file as input

For example, we can use the following command line to apply the masking information, created above, to the existing BLAST database generated in Obtaining sample data for this cookbook entry:

```
$ makeblastdb -in hs_chr -input_type blastdb -dbtype nucl -parse_seqids \
-mask_data hs_chr_mask.asnb -out hs_chr -title \
"Human Chromosome, Ref B37.1"
```

Here, we use the existing BLAST database as input file (-in hs_chr), specify its type (-dbtype nucl), enable parsing of sequence ids (-parse_seqids), provide the masking data (-mask_data hs_chr_mask.asnb), and name the output database with the same base name (-out hs_chr) overwriting the existing one.

To use the original FASTA sequence file (hs_chr.fa) as the input, we need to use “-in hs_chr.fa” to instruct makeblastdb to use that FASTA file instead.

We can check the “re-created” database to find out if the masking information was added properly, using blastdbcmd with the following command line:

```
$ blastdbcmd -db hs_chr -info
```

This command prints out a summary of the target database:

```
Database: human chromosomes, Ref B37.1
         24 sequences; 3,095,677,412 total bases

Date: Aug 13, 2009  3:02 PM      Longest sequence: 249,250,621 bases

Available filtering algorithms applied to database sequences:

Algorithm ID  Algorithm name      Algorithm options
    30         windowmasker

Volumes:
    /export/home/tao/blast_test/hs_chr
```

Extra lines under the “Available filtering algorithms ...” describe the masking algorithms available. The “Algorithm ID” field, 30 in our case, is what we need to use if we want to invoke database soft masking during an actual search through the “-db_soft_mask” parameter.

We can apply additional masking data to an existing BLAST database with one type of masking information already added. For example, we can apply the dust masking generated above to the database generated earlier by using this command line:

```
$ makeblastdb -in hs_chr -input_type blastdb -dbtype nucl -parse_seqids \
-mask_data hs_chr_dust.asnb -out hs_chr -title "Human Chromosome, Ref B37.1"
```

Here, we use the existing database as input file (-in hs_chr), specify its input and molecule type (-input_type blastdb -dbtype nucl), enable parsing of sequence ids (-parse_seqids), provide the dust masking data (-mask_data hs_chr_dust.asnb), naming the database with the same based name (-out hs_chr) overwriting the existing one.

Checking the “re-generated” database with blastdbcmd:

```
$ blastdbcmd -db hs_chr -info
```

we can see that both sets of masking information are available:

```
Database: Human Chromosome, Ref B37.1
         24 sequences; 3,095,677,412 total bases

Date: Aug 25, 2009  4:43 PM      Longest sequence: 249,250,621 bases

Available filtering algorithms applied to database sequences:

Algorithm ID  Algorithm name      Algorithm options
    11         dust          window=64; level=20; linker=1
    30        windowmasker
```

```
Volumes:
         /net/gizmo4/export/home/tao/blast_test/hs_chr
```

A more straightforward approach to apply multiple sets of masking information in a single makeblastdb run by providing multiple set of masking data files in a comma delimited list:

```
$ makeblastdb -in hs_chr -input_type blastdb -dbtype nucl -parse_seqids \
  -mask_data hs_chr_dust.asnb, hs_chr_mask.asnb -out hs_chr
```

Create a protein BLAST database with masking information

We can use the masking data file generated in “Create masking information using segmasker” to create a protein BLAST database:

```
$ makeblastdb -in refseq_protein -input_type blastdb -dbtype prot -parse_seqids \
  -mask_data refseq_seg.asnb -out refseq_protein -title \
  "RefSeq Protein Database"
```

Using blastdbcmd, we can check the database thus generated:

```
$ blastdbcmd -db refseq_protein -info
```

This produces the following summary, which includes the masking information:

```
Database: RefSeq Protein Database
         7,044,477 sequences; 2,469,203,411 total residues

Date: Sep 1, 2009  10:50 AM      Longest sequence: 36,805 residues

Available filtering algorithms applied to database sequences:

Algorithm ID  Algorithm name      Algorithm options
    21         seg          window=12; locut=2.2; hicut=2.5
```

```
Volumes:
         /export/home/tao/blast_test/refseq_protein2.00
         /export/home/tao/blast_test/refseq_protein2.01
         /export/home/tao/blast_test/refseq_protein2.02
```

Create a nucleotide BLAST database using the masking information extracted from lower case masked FASTA file

We use the following command line:

```
$ makeblastdb -in hs_chr.mfa -dbtype nucl -parse_seqids \
  -mask_data hs_chr_mfa.asnb -out hs_chr_mfa -title "Human chromosomes (mfa)"
```

Here we use the lowercase masked FASTA sequence file as input (-in hs_chr.mfa), its file type (-input_type fasta), specify the database as nucleotide (-dbtype nucl), enable parsing of sequence ids (-parse_seqids), provide the masking data (-mask_data hs_chr_mfa.asnb), and name the resulting database as hs_chr_mfa (-out hs_chr_mfa).

Checking the database thus generated using blastdbcmd, we have:

```
Database: Human chromosomes (mfa)
      24 sequences; 3,095,677,412 total bases

Date: Aug 26, 2009  11:41 AM      Longest sequence: 249,250,621 bases

Available filtering algorithms applied to database sequences:

Algorithm ID   Algorithm name      Algorithm options
      40         repeat          repeatmasker lowercase

Volumes:
      /export/home/tao/hs_chr_mfa
```

The algorithm name and algorithm options are the values we provided in “Extract masking information from FASTA sequences with lowercase masking”.

Obtaining Sample data for this cookbook entry

For input nucleotide sequences, we use the BLAST database generated from a FASTA input file hs_chr.fa, containing complete human chromosomes from BUILD38, generated by inflating and combining the hs_ref_*.fa.gz files located at:

```
ftp.ncbi.nlm.nih.gov/genomes/H_sapiens/Assembled_chromosomes/seq/
```

We use this command line to create the BLAST database from the input nucleotide sequences:

```
$ makeblastdb -in hs_chr.fa -dbtype nucl -parse_seqids \
  -out hs_chr -title "Human chromosomes, Ref B38"
```

For input nucleotide sequences with lowercase masking, we use the FASTA file hs_chr.mfa, containing the complete human chromosomes from BUILD37.1, generated by inflating and combining the hs_ref_*.mfa.gz files located in the same ftp directory.

For input protein sequences, we use the preformatted refseq_protein database from the NCBI blast/db/ ftp directory:

```
ftp.ncbi.nlm.nih.gov/blast/db/refseq_protein.00.tar.gz
ftp.ncbi.nlm.nih.gov/blast/db/refseq_protein.01.tar.gz
ftp.ncbi.nlm.nih.gov/blast/db/refseq_protein.02.tar.gz
```

Search with database masking enabled

Created: June 23, 2008; Updated: January 7, 2021.

Database masking has two modes. The first is known as "soft-masking", and BLAST uses the database mask only during the (initial) word-finding phase of BLAST. The second is known as "hard-masking", and BLAST uses the database mask during all phases of the search. Here, we look at both types of masking.

To enable database masking during a BLAST search, we use the `-info` parameter of `blastdbcmd` to discover the masking Algorithm ID. For the database generated in the previous cookbook entry, we can use the following command line to activate the windowmasker soft masking:

```
$ blastn -query HTT_gene -task megablast -db hs_chr -db_soft_mask 30 \
  -outfmt 7 -out HTT_megablast_softmask.out -num_threads 4
```

Here, we search a nucleotide query, `HTT_gene*` (`-query HTT_gene`), with the megablast algorithm (`-task megablast`) against the database `hs_chr` (`-db hs_chr`). We use soft masking (`-db_soft_mask 30`), set the result format to tabular output (`-outfmt 7`), and save the result to a file named `HTT_megablast_softmask.tab` (`-out HTT_megablast_softmask.tab`). We also activated the multi-threaded feature of `blastn` to speed up the search by using 4 CPUs^{\$} (`-num_threads 4`).

For the database generated in the previous cookbook entry, we can use the following command line to activate the windowmasker hard masking:

```
$ blastn -query HTT_gene -task megablast -db hs_chr -db_hard_mask 30 \
  -outfmt 7 -out HTT_megablast_hardmask.out -num_threads 4
```

The options are similar to the ones for soft masking, except that we use `-db_hard_mask` rather than `-db_soft_mask`. Additionally, we changed the name of the output file.

Hard masking is much more aggressive than soft masking. In interspersed or simple repeats, soft masking normally provides the best results. Hard masking may be warranted to remove vector or other contamination from the BLAST results.

*This is a genomic fragment containing the HTT gene from human, including 5 kb up- and down-stream of the transcribed region. It is represented by NG_009378.

\$ The number to use under in your run will depend on the number of CPUs your system has.

In a test run under a 64-bits Linux machine, the search with soft masking took about 1.5 seconds real time, and the search with hard masking took about 2.5 seconds real time. The search without database masking took about 31 minutes.

Display BLAST search results with custom output format

Created: June 23, 2008; Updated: January 7, 2021.

The `-outfmt` option permits formatting arbitrary fields from the BLAST tabular and comma-separated-value (CSV) formats. Use the `-help` option on the command-line application (e.g., `blastn`) to see the supported fields. The `max_target_seqs` option should be used with any tabular output to control the number of matches reported.

Example of custom output format: field selection

The following example shows how to display the results of a BLAST search using a custom output format. The tabular output format with comments is used, but only the query accession, subject accession, evaluate, query start, query stop, subject start, and subject stop are requested. For brevity, only the first 10 lines of output are shown:

```
$ echo 1786181 | ./blastn -db ecoli -outfmt "7 qacc sacc evaluate
qstart qend sstart send"
# BLASTN 2.2.18+
# Query: gi|1786181|gb|AE000111.1|AE000111
# Database: ecoli
# Fields: query acc., subject acc., evaluate, q. start, q. end, s.
start, s. end
# 85 hits found
AE000111 AE000111 0.0 1 10596 1 10596
AE000111 AE000174 8e-30 5565 5671 6928 6821
AE000111 AE000394 1e-27 5587 5671 135 219
AE000111 AE000425 6e-26 5587 5671 8552 8468
AE000111 AE000171 3e-24 5587 5671 2214 2130
$
```

Example of custom output format: output separator

One can also customize the output separator in the tabular and comma-separated-value output formats using the `delim` token immediately after the numeric output format selector. In the example below `@` is used as a custom output separator:

```
$ echo 1786181 | blastn -db ecoli -outfmt '6 delim=@' | head
AE000111.1@AE000111.1@100.000@10596@0@0@1@10596@1@10596@0.0@19568
AE000111.1@AE000174.1@88.991@109@9@3@5565@5671@6928@6821@7.69e-30@132
AE000111.1@AE000394.1@92.941@85@6@0@5587@5671@135@219@1.29e-27@124
AE000111.1@AE000425.1@91.860@86@5@2@5587@5671@8552@8468@5.99e-26@119
AE000111.1@AE000171.1@90.588@85@8@0@5587@5671@2214@2130@2.78e-24@113
AE000111.1@AE000171.1@90.476@84@8@0@5587@5670@10559@10642@1.00e-23@111

```

Trace-back operations (BTOP)

The “Blast trace-back operations” (BTOP) string describes the alignment produced by BLAST. This string is similar to the CIGAR string produced in SAM format, but there are important differences. BTOP is a more flexible format that lists not only the aligned region but also matches and mismatches. BTOP operations consist of 1.) a number with a count of matching letters, 2.) two letters showing a mismatch (e.g., “AG” means A was

replaced by G), or 3.) a dash (“-”) and a letter showing a gap. The box below shows a blastn run first with BTOP output and then the same run with the BLAST report showing the alignments.

```
$ blastn -query test_q.fa -subject test_s.fa -dust no -outfmt "6
qseqid sseqid btop" -parse_deflines
query1  q_multi 7AG39
query1  q_multi 7A-39
query1  q_multi 6-G-A41
$ blastn -query test_q.fa -subject test_s.fa -dust no -parse_deflines
BLASTN 2.2.24+
```

```
Query= query1
Length=47
```

```
Subject=
Length=142
```

```
Score = 82.4 bits (44), Expect = 9e-22

Use `blastdb_aliastool` to manage the BLAST databases

Created: June 23, 2008; Updated: January 7, 2021.

Often, one needs to search multiple databases together or wishes to search a specific subset of sequences within an existing database. For these type of searches a convenient way to conduct them is by creating a virtual BLAST database. The `blastdb_aliastool` can perform three types of tasks to assist in that process. First, it can build an alias file to transparently combine searches of different databases. Second, it can build an alias file that limits a search based on a list of GIs (numerical IDs) or accessions. Finally, it can convert the list of GI's or accessions to a more efficient binary format.

Note: When combining BLAST databases, all the databases must be of the same molecule type. The following examples assume that the two databases as well as the GI file are in the current working directory. The binary format for accessions is only supported in the newer version 5 of the BLAST databases (BLAST+ 2.10.0 or newer suggested). Version 5 of the BLAST databases supports limiting a search natively by taxonomy, and only the relevant TAXIDs are needed.

Aggregate existing BLAST databases

To combine the two nematode nucleotide databases, named “`nematode_mrna`” and “`nematode_genomic`”, we use the following command line:

```
$ blastdb_aliastool -dblist "nematode_mrna nematode_genomic" -dbtype nucl \
  -out nematode_all -title "Nematode RefSeq mRNA + Genomic"
```

Create a subset of a BLAST database

The `nematode_mrna` database contains RefSeq mRNAs for several species of round worms. The best subset is from *C. elegans*. In most cases, we want to search this subset instead of the complete collection. Since the database entries are from NCBI nucleotide databases and the database is formatted with “-parse_seqids”, we can use the “-gilist `c_elegans_mrna.gi`” parameter/value pair to limit the search to the subset of interest, alternatively, we can create a subset of the `nematode_mrna` database as follows:

```
$ blastdb_aliastool -db nematode_mrna -gilist c_elegans_mrna.gi -dbtype \
  nucl -out c_elegans_mrna -title "C. elegans refseq mRNA entries"
```

Note: one can also specify multiple databases using the `-db` parameter of `blastdb_aliastool`.

Convert a GI or accession list to binary format

The `blastdb_aliastool` can convert a GI or accession list to a binary format that is more efficient during the BLAST search. The example below converts a list of accessions to the binary format. The last two options shown (`-seqid_db` and `-seqid_dbtype`) are optional and limit the contents of the resulting accession list to accessions in the specified database, in this case `swissprot`. This may result in a much smaller file and shorter run times, but BLAST will exit with an error if the specified database is not used. As mentioned earlier, binary accession lists are only supported with version 5 BLAST databases.

```
$ blastdb_aliastool -seqid_file_in myacc.acc -seqid_file_out myacc.bin.acc -seqid_db
swissprot -seqid_dbtype prot
```

Reformat BLAST reports with blast_formatter

Created: June 23, 2008; Updated: January 7, 2021.

It may be helpful to view the same BLAST results in different formats. A user may first parse the tabular format looking for matches meeting a certain criteria, then go back and examine the relevant alignments in the full BLAST report. He may also first look at pair-wise alignments, then decide to use a query-anchored view. Viewing a BLAST report in different formats has been possible on the NCBI BLAST web site since 2000, but has not been possible with stand-alone BLAST runs. The `blast_formatter` allows this, if the original search produced blast archive format using the `-outfmt 11` switch. The query sequence, the BLAST options, the masking information, the name of the database, and the alignment are written out as ASN.1 (a structured format similar to XML). The `-max_target_seqs` option should be used to control the number of matches recorded in the alignment. The `blast_formatter` reads this information and formats a report. The BLAST database used for the original search must be available, or the sequences need to be fetched from the NCBI, assuming the database contains sequences in the public dataset. The box below illustrates the procedure. A `blastn` run first produces the BLAST archive format, and the `blast_formatter` then reads the file and produces tabular output.

`blast_formatter` will format stand-alone searches performed with an earlier version of a database if both the search and formatting databases are prepared so that fetching by sequence ID is possible. To enable fetching by sequence ID use the `-parse_seqids` flag when running `makeblastdb`, or (if available) download preformatted BLAST databases from <ftp://ftp.ncbi.nlm.nih.gov/blast/db/> using `update_blastdb.pl` (provided as part of the BLAST+ package). Currently the blast archive format and `blast_formatter` do not work with database free searches (i.e., `-subject` rather than `-db` was used for the original search).

```
$ echo 1786181 | blastn -db ecoli -outfmt 11 -out out.1786181.asn
$ blast_formatter -archive out.1786181.asn -outfmt "7 qacc sacc evalue
qstart qend sstart send"

Extracting data from BLAST databases with blastdbcmd

Created: June 23, 2008; Updated: January 7, 2021.

Extract lowercase masked FASTA from a BLAST database with masking information

If a BLAST database contains masking information, this can be extracted using the blastdbcmd options –db_mask and –mask_sequence as follows:

```
$ blastdbcmd -info -db mask-data-db
Database: Mask data test
        10 sequences; 12,609 total residues
```

```
Date: Feb 17, 2009  5:10 PM      Longest sequence: 1,694 residues
```

Available filtering algorithms applied to database sequences:

Algorithm ID	Algorithm name	Algorithm options
20	seg	default options used
40	repeat	-species Desmodus_rotundus

Volumes:

mask-data-db

```
$ blastdbcmd -db mask-data-db -mask_sequence_with 20 -entry 71022837
>gi|71022837|ref|XP_761648.1| hypothetical protein UM05501.1 [Ustilago maydis 521]

Custom data extraction and formatting from a BLAST database

The following examples show how to extract selected information from a BLAST database and how to format it:

Extract the accession, sequence length,
and masked locations for GI 71022837:

```
$ blastdbcmd -entry 71022837 -db Test/mask-data-db -outfmt "%a %l %m"
XP_761648.1 1292 119-139;140-144;147-152;154-160;161-216;
```

Extract different sequence ranges from the BLAST databases

The command below will extract two different sequences: bases 40-80 in human chromosome Y (GI 13626247) with the masked regions in lowercase characters (notice argument 30, the masking algorithm ID which is available in this BLAST database) and bases 1-10 in the minus strand of human chromosome 20 (GI 14772189).

```
$ printf "%s %s %s %s\n%s %s %s\n" 13626247 40-80 plus 30 14772189 1-10 minus \
| blastdbcmd -db GPIPE/9606/current/all_contig -entry_batch -
>gi|13626247|ref|NT_025975.2|:40-80 Homo sapiens chromosome Y genomic contig, GRCh37.p10
Primary Assembly
tgcattccattctattctcttctACTGCATACAatttcact
>gi|14772189|ref|NT_025215.4|:c10-1 Homo sapiens chromosome 20 genomic contig, GRCh37.p10
Primary Assembly
GCTCTAGATC
$
```

Display the locations where BLAST will search for BLAST databases

This is accomplished by using the `-show_blastdb_search_path` option in `blastdbcmd`:

```
$ blastdbcmd -show_blastdb_search_path
:/net/nabl000/vol/blast/db/blast1:/net/nabl000/vol/blast/db/blast2:
$
```

Display the available BLAST databases at a given directory

This is accomplished by using the `-list` option in `blastdbcmd`:

```
$ blastdbcmd -list repeat -recursive
repeat/repeat_3055 Nucleotide
repeat/repeat_31032 Nucleotide
repeat/repeat_35128 Nucleotide
repeat/repeat_3702 Nucleotide
repeat/repeat_40674 Nucleotide
repeat/repeat_4530 Nucleotide
repeat/repeat_4751 Nucleotide
repeat/repeat_6238 Nucleotide
repeat/repeat_6239 Nucleotide
repeat/repeat_7165 Nucleotide
repeat/repeat_7227 Nucleotide
repeat/repeat_7719 Nucleotide
repeat/repeat_7955 Nucleotide
repeat/repeat_9606 Nucleotide
repeat/repeat_9989 Nucleotide
$
```

The first column of the default output is the file name of the BLAST database (usually provided as the `-db` argument to other BLAST+ applications), the second column represents the molecule type of the BLAST database. This output is configurable via the `list_outfmt` command line option.

Use Windowmasker to filter the query sequence(s) in a BLAST search

Created: June 23, 2008; Updated: January 7, 2021.

The `blastn` executable can filter a query sequence using the windowmasker data files. This option can be used to mask interspersed repeats that may lead to spurious matches. The windowmasker data files should be created as discussed in step 1 of “Create masking information using windowmasker” or downloaded from the NCBI FTP site. Follow the instructions in Configuring BLAST to make sure BLAST will be able to find the windowmasker files in the examples below.

1. Run BLAST search using Windowmasker for sequence filtering based upon taxid (9606 is the taxid for human).

```
$ blastn -query input -db database -window_masker_taxid 9606 -out results.txt
```

2. Run BLAST search using Windowmasker for sequence filtering based upon the windowmasker file name.

```
$ blastn -query input -db database -window_masker_db 9606/wmasker.obinary
```

Building a BLAST database with your (local) sequences

Created: June 23, 2008; Updated: January 7, 2021.

If you would like to search the BLAST databases NCBI offers, please see [Get NCBI BLAST databases](#)

The `makeblastdb` application produces BLAST databases from FASTA files. It is possible to use completely unstructured (or even blank) FASTA definition lines, but this is not the recommended procedure. Assigning a unique identifier to every sequence in the database allows you to retrieve the sequence by identifier and allows you to associate every sequence with a taxonomic node (through the `taxid` of the sequence). The unique identifier can be a simple string (as in the example below) or could be actual accession of the sequence if the sequence comes from a public database (e.g., GenBank). Being able to associate a database sequence with a taxonomic node is especially powerful for the version 5 databases that BLAST can use to limit the search by taxonomy. The identifier should begin right after the “>” sign on the definition line and contain no spaces and the `-parse_seqids` flag should be used. In general, you should not use a “|” (bar) in your identifier. The “|” (bar) is a reserved character for the NCBI FASTA ID parser and `makeblastdb` will return an error unless the bar is used in a specific manner described at https://ncbi.github.io/cxx-toolkit/pages/ch_demo#ch_demo.T5

An example FASTA file is:

```
$ cat test.fsa
>seq1
MSFSTKPLDMATWPDFAALVERHNGVWGGCWCMAFHAKGSGAVGNREAKEARVREGSTHAALVFDGSACVGWCQFGPTGE
LPRIKHLRAYEDGQAVLPDWITCFFSDKAFRGKGVAALAGALAEIGRLGGGTVESYPEDAQGRTVAGAFLNHGTLM

LFRPPDVLGPEIELSLTRSDGWLMLVVENKGASRLRRSDVTLAQGSAGIARREGFVGYVLPGLTRHWRVGREDSYSGGIV
TVSANSSGGAIGEQLVVSGR
>seq6
TTLQLQVPIGWGLVHQGGALVVLGFAIAHWRGFVGTYTRDTAIEMRD
```

An additional (optional) file mapping the identifiers to taxids (a number identifying a taxonomic node) may be used to associate each sequence with a taxonomic node.

```
$ cat test_map.txt
seq1 68287
seq2 2382161
seq3 68287
seq4 382
seq5 382
seq6 382
```

The `taxid` for a taxonomic node can be looked up with the `get_species_taxids.sh` script distributed with the BLAST+. Additionally, the NCBI provides other resources. The files in <https://ftp.ncbi.nlm.nih.gov/pub/taxonomy/accession2taxid/> provide a mapping from accession to `taxid` (useful if the sequences are from a public

database). Information on other taxonomy files is available at <https://ncbiinsights.ncbi.nlm.nih.gov/2018/02/22/new-taxonomy-files-available-with-lineage-type-and-host-information/> Finally, https://www.ncbi.nlm.nih.gov/Taxonomy/TaxIdentifier/tax_identifier.cgi provides a means to perform species name to taxid lookups

Makeblastdb can be invoked for the FASTA and (optional) taxid mapping files as below. We use the -blastdb_version parameter to construct a version 5 database and the -taxid_map parameter to associate each sequence with a taxonomic node. Note that we also use -parse_seqids.

```
$ makeblastdb -in test.fsa -parse_seqids -blastdb_version 5 -taxid_map test_map.txt -
title "Cookbook demo" -dbtype prot
```

```
Building a new DB, current time: 02/06/2019 17:08:14
New DB name:   test.fsa
New DB title:  Cookbook demo
Sequence type: Protein
Keep MBits: T
Maximum file size: 1000000000B
Adding sequences from FASTA; added 6 sequences in 0.00222588 seconds.
$
```

If you do add the taxids to your database, make sure you have the BLAST taxonomy data files (taxdb.bt[di]) which are available from <https://ftp.ncbi.nlm.nih.gov/blast/db/> but also packaged with most BLAST databases distributed by the NCBI.

If all of the sequences in your database have the same taxid, you can simply use the -taxid flag on makeblastdb to associate all sequences with that taxid rather than needing to prepare a file.

For releases prior to BLAST+ 2.9.0, ad hoc identifiers (as shown in our example above) should be prefixed with “lcl|” (e.g., lcl|seq1 in place of seq1) for the taxid mapping file.

The NCBI makes databases that are searchable on the NCBI web site (such as nr, refseq_rna, and swissprot) available on its FTP site. It is better to download the preformatted databases rather than starting with FASTA. The databases on the FTP site contain taxonomic information for each sequence, include the identifier indices for lookups, and can be up to four times smaller than the FASTA. The original FASTA can be generated from the BLAST database using blastdbcmd.

Starting with the 2.10.0 release, makeblastdb produces version 5 databases by default, which uses LMDB. LMDB requires virtual memory (at least 600 GB, but 800 GB is recommended). Virtual memory is just that (virtual) and doesn't depend on the hardware in your system. In general, we recommend that BLAST users simply set the virtual memory to unlimited.

Limiting a Search by taxonomy

Created: June 23, 2008; Updated: January 7, 2021.

In order to limit a BLAST search by taxonomy, one needs to provide the NCBI taxonomy ID(s) (taxid) for given organism(s). A taxid is simply a number that specifies a node in the taxonomic tree. For example, 9606 is the taxid for human, 9989 is the taxid for rodentia, and 2 is the taxid for all bacteria. Taxids are preferable to organism names as the latter can be ambiguous. For instance, bacteria is both a genus of insects as well as a superkingdom. **BLAST only accepts taxids that are at or below the species level.**

The BLAST+ command line tool suite provides the `get_species_taxids.sh` script to translate higher level taxids (e.g.: Enterobacterales) into a list of taxids that are at the appropriate level. This script can also be used to look up (and disambiguate) taxids based upon a taxonomic name. If unsure whether your taxid is at the species level or lower, it is safe to run `get_species_taxids.sh` and feed the output to BLAST.

Additionally, one may use the `-negative_taxids` and `-negative_taxidlist` options to exclude sequences by taxid.

Note: this script depends on EDirect and it only works on Linux and Mac. For EDirect installation instructions, please see <https://www.ncbi.nlm.nih.gov/books/NBK179288/>.

Limiting a BLAST search with a high-level taxonomic node

```
$ get_species_taxids.sh -n Enterobacterales
Taxid: 91347
rank: order
division: enterobacteria
scientific name: Enterobacterales
common name:
1 matches found
$ get_species_taxids.sh -t 91347 > 91347.txids
$ blastn -db nt -query QUERY -taxidlist 91347.txids -outfmt 7 -out OUTPUT.tab
```

Limiting a BLAST search with a species-level taxonomic node

```
$ blastn -db nt -query QUERY -taxids 9606 -outfmt 7 -out OUTPUT.tab
```

Limiting a Search with a List of Identifiers

Created: June 23, 2008; Updated: January 7, 2021.

BLAST can also limit a database search by a list of identifiers (e.g.: accessions), which should be specified one per line in a file. These identifiers, referencing the sequences to include or exclude in the BLAST search, should not contain any whitespace and should be retrievable from the BLAST database.

Starting with BLASTDB version 5, an accession list must be pre-processed before it can be used in a search. This process checks that the accessions appear to be real and produces a file optimized for use with BLAST. It is also possible to confirm that all the accessions are actually in the target database. The examples below demonstrate this functionality:

```
# 9606.pacc is a text file with protein accessions. This command produces a file called 9606.pacc.bsl
$ blastdb_aliastool -seqid_file_in 9606.pacc
```

```
# This command searches nr limited to the accessions in the file 9606.pacc.bsl
$ blastp -db nr -query QUERY.fsa -outfmt "7 std taxid" -seqidlist 9606.pacc.bsl
```

Additionally, one may use the `-negative_seqidlist` option to exclude sequences by accession from the BLAST search.

When the search is limited by a list of IDs the statistics of the BLAST database are re-calculated to reflect the actual number of sequences and residues/bases included in the search.

Multiple databases vs. spaces in filenames and paths

Created: June 23, 2008; Updated: January 7, 2021.

BLAST has been able to search multiple databases since 1997. The databases can be listed after the “-db” argument or in an alias file (see cookbook entries on `blastdb_aliastool`), separated by spaces. Many operating systems now allow spaces in filenames and directory paths, so some care is required. Basically, one should always have two sets of quotes for any path containing a space. `blastdbcmd` is used as an example below, but the same rules apply to `makeblastdb` as well as the search programs like `blastn` or `blastp`.

To access a BLAST database containing spaces under Microsoft Windows it is necessary to use two sets of double-quotes, escaping the innermost quotes with a backslash. For example, `Users\joeuser\My Documents\Downloads` would be accessed by:

```
blastdbcmd -db "\"Users\joeuser\My Documents\Downloads\mydb\" \" -info
```

The first backslash escapes the beginning inner quote, and the backslash following “mydb” escapes the ending inner quote.

A second database can be added to this command by including it within the outer pair of quotes:

```
blastdbcmd -db "\"Users\joeuser\My Documents\Downloads\mydb\" myotherdb\" -info
```

If the second database had contained a space, it would have been necessary to surround it by quotes escaped by a backslash.

Under UNIX systems (including LINUX and Mac OS X) it is preferable to use a single quote (‘) in place of the escaped double quote:

```
blastdbcmd -db ` "path with spaces/mydb" ` -info
```

Multiple databases can also be listed within the single quotes, similar to the procedure described for Microsoft Windows.

Specifying a sequence as the multiple sequence alignment master in psiblast

Created: June 23, 2008; Updated: January 7, 2021.

The `-in_msa` psiblast option, unlike blastpgp, does not support the specification of a master sequence via the `-query` option, so if one wants to specify a sequence (other than the first one) in the multiple sequence alignment file to be the master sequence, this has to be specified via the `-msa_master_idx` option. For instance, in the example below, the third sequence in the multiple sequence alignment would be used as the master sequence:

```
psiblast -in_msa align1 -db pataa -msa_master_idx 3
```

Ignoring the consensus sequence in the multiple sequence alignment in psiblast

Created: June 23, 2008; Updated: January 7, 2021.

Often a consensus sequence is added to a multiple sequence alignment to be used as the master sequence in a PSI-BLAST search. The consensus sequence provides a good option to display the query-subject alignment in the output and to define which MSA columns are to be converted to PSSM. At the same time adding the consensus sequence changes the statistical properties of the original alignment. To avoid this, the `-ignore_msa_master` option can be used:

```
psiblast -in_msa align1 -db pataa -ignore_msa_master
```

In this case the master sequence is displayed in the output but ignored when the PSSM scores are calculated.

Performing a DELTA-BLAST search

Created: June 23, 2008; Updated: January 7, 2021.

DELTA-BLAST searches a protein sequence database using a PSSM constructed from conserved domains matching a query. It first searches the NCBI CDD database to construct the PSSM.

Download the cdd_delta database

Obtain this database from <ftp://ftp.ncbi.nlm.nih.gov/blast/db> using the `update_blastdb.pl` tool (provided as part of the BLAST+ package). Note that the `cdd_delta` database must be downloaded and installed to the standard BLAST database directory (see Configuring BLAST) or in the current working directory.

Execute the deltablast search

```
$ deltablast -query query.fsa -db pataa
```

Indexed megaBLAST search

The indexed megaBLAST search requires both BLAST databases as well as an index of the words found in the database. The index of words may be produced with `makembindex`. The example below demonstrates how to produce the index as well as perform an indexed megaBLAST search. This example assumes that the `nt.00` BLAST database has been placed in the current directory (before `makembindex` is run) and that `QUERY` is a file containing a nucleotide query. Results will appear in `OUTPUT`. See tables C2 and C11 for information on command-line options.

```
$ makembindex -input nt.00 -ifformat blastdb -old_style_index false
$ blastn -db ./nt.00 -query QUERY -use_index true -out OUTPUT
```

The BLAST databases may contain filtering (or masking) information for the database sequences. `Makembindex` can access this information and exclude the masked regions of the database from the index. This is demonstrated below. The first command shows how to discover the masking “Algorithm ID” from the BLAST database using `blastdbcmd`. In this case, the ID is 30. The second command demonstrates how to build an index that excludes the masked regions. Once the index has been built, it can be used as shown above. In the example below, the `ref_contig` BLAST database had been placed in the directory before `makembindex` was run.

```
$ blastdbcmd -db ref_contig -info
Database: ref_contig
364 sequences; 2,938,626,560 total bases
```

```
Date: Oct 7, 2011 10:34 AM    Longest sequence: 115,591,997 bases
```

```
Available filtering algorithms applied to database sequences:
```

Algorithm ID	Algorithm name	Algorithm options
30	windowmasker	default options used

```
$ makembindex -input ref_contig -ifformat blastdb -old_style_index false -db_mask 30
creating /export/home/madden/INDEX_TEMP/ref_contig.00.idx...done
creating /export/home/madden/INDEX_TEMP/ref_contig.01.idx...done
creating /export/home/madden/INDEX_TEMP/ref_contig.02.idx...removed (empty)
```

BLAST+ remote service

The BLAST+ applications can perform a search on the NCBI servers if invoked with the “-remote” flag. All other command-line options are the same as for a stand-alone search.

The box below shows an example BLAST+ remote search using the `blastn` application. First, `blastn` searches the query against the `nt` database and produces a standard BLAST report. The query file (`nt.u00001`) contains the sequence for accession `u00001` as FASTA. Second, the UNIX `grep` utility is used to find the RID for the search. Note that the RID can simply be found near the top of the BLAST report. Third, the RID is then used with `blast_formatter` to print out the results as a tabular report. Finally, the results are formatted as XML. The RID is only printed as an example and is no longer valid.

```
$ blastn -db nt -query nt.u00001 -out test.out -remote
$ grep RID test.out
RID: X3R7GAUS014

$blast_formatter -rid X3R7GAUS014 -out test.tab -outfmt 7

$blast_formatter -rid X3R7GAUS014 -out test.xml -outfmt 5
```

Query a BLAST database with an accession, but exclude that accession from the results

Created: June 23, 2008; Updated: January 7, 2021.

```
# Extract a GI from the ecoli database:
$ blastdbcmd -entry all -db ecoli -dbtype nucl -outfmt %a | head -1 | \
  tee exclude_me
AE000111.1
# Run the restricted database search, which shows there are no self-hits:
$ blastn -db ecoli -negative_seqidlist exclude_me -show_gis -num_alignments 0 \
  -query exclude_me | grep `cat exclude_me`
Query= AE000111.1 Escherichia coli K-12 MG1655 section 1 of 400 of the
$
```

Faster sequence lookups by accession

Created: June 23, 2008; Updated: January 7, 2021.

Starting with BLASTDB version 5, `blastdbcmd` has two additional parameters (`-taxids` and `-taxidlists`) to efficiently retrieve sequences by `taxid`.

```
# Retrieves all human entries;
# %a prints the accession, %T prints the taxid, %S prints the scientific name
$ blastdbcmd -db nr -taxids 9606 -outfmt "%a %T %S" -target_only
```

Note: `-target_only` is used to ensure that only accessions for the human entries are present. Otherwise, it will present all accessions on any sequence with at least one human sequence. This is important since `nr` is a non-redundant database.

Threading By Query

Tom Madden

Created: June 23, 2008; Updated: June 28, 2021.

Starting in the 2.12.0 release, BLAST supports a different threading model that can be more efficient in certain situations. This section describes how and when to use that option.

Traditionally, BLAST multi-threads by having each thread work on a subset of the database. Some parts of this process are single threaded (such as setup and formatting), but for large databases such as nt or nr, this is not significant. For smaller databases, performance can be poor. We have implemented a multi-threading option that can be advantageous for batch processing. It works well if you have large numbers of queries with a small database or limit your search by taxid or by gilst. This option takes many query sequences and assigns them to a thread, which performs the entire search and formatting of results within that thread. All threads work independently, eliminating bottlenecks. The order of the query sequences is preserved in the results. We call this “threading by query”.

You may enable threading by query with the `-mt_mode` option by providing a value of 1, as shown below. The default value for the `-mt_mode` option is 0. You still specify the number of threads with the “`-num_threads`” option.

```
$ blastp -db swissprot -query BIGFASTA.fsa -out test.out -num_threads 32 -mt_mode 1
```

As noted above, the threading by query option works well with relatively small databases if you have a lot of queries to process. For BLASTP, your input FASTA should contain at least 10,000 residues per thread, or 320,000 residues for 32 threads. For BLASTX, the FASTA should contain 30,000 bases per thread. For both BLASTP and BLASTX, we find threading by query works best if the database has fewer than 2 billion residues (e.g, swissprot). For BLASTN, your FASTA file should contain at least 2.5 million bases per thread and the database should contain fewer than 14 billion residues. Threading by query also works well if you limit the search, such as by `-taxid` or `-gilst`, regardless of the size of the database.

Here, we show some examples where this strategy works well. Below, the orange lines shows results for threading by query (`mt_mode=1`), where each thread works independently on a batch of sequences. The blue line shows the default method appropriate for large databases or few queries.

MegaBLAST search of 1,966 sequences (899,809,898 bp) from the Sander lucioperca betanodavirus, whole genome shotgun sequencing project (<https://www.ncbi.nlm.nih.gov/nuccore/CABPSU000000000.1>) against the refseq viral representative genomes database. For 32 threads, the search can be completed more than four times faster (84 vs. 368 seconds) when threading by query.

BLASTP search of 20,410 proteins from the human gut metagenome WGS project (<https://www.ncbi.nlm.nih.gov/Traces/wgs/AJWY01>) against swissprot. For 32 threads, the search is 2.8 times faster (3.4 minutes vs 9.5 minutes) when threading by query. The task blastp-fast was used.

BLASTP search of 9200 proteins from the refseq_select protein database against refseq_protein limited to human entries with -taxid flag. For 32 threads, the search is 5.7 times faster (14 minutes vs 80 minutes) when threading by query. The task blastp-fast was used.

Conversion from C toolkit applications

The functionality offered by the BLAST+ applications has been organized by program type. The following graph depicts a correspondence between the NCBI C Toolkit BLAST command line applications and the BLAST+ applications:

The easiest way to get started using the BLAST+ command line applications is by means of the `legacy_blast.pl` PERL script which is bundled along with the BLAST+ applications. To utilize this script, simply prefix it to the invocation of the C toolkit BLAST command line application and append the `--path` option pointing to the installation directory of the BLAST+ applications. For example, instead of using

```
blastall -i query -d nr -o blast.out
```

use

```
legacy_blast.pl blastall -i query -d nr -o blast.out
--path /opt/blast/bin
```

The purpose of the `legacy_blast.pl` PERL script is to help users make the transition from the C Toolkit BLAST command line applications to the BLAST+ applications. This script produces its own documentation by invoking it without any arguments.

The `legacy_blast.pl` script supports two modes of operation, one in which the C Toolkit BLAST command line invocation is converted and executed on behalf of the user and another which solely displays the BLAST+ application equivalent to what was provided, without executing the command.

The first mode of operation is achieved by specifying the C Toolkit BLAST command line application invocation and optionally providing the `--path` argument after the command line to convert if the installation path for the BLAST+ applications differs from the default (available by invoking the script without arguments). See example in the first section of the Quick start.

The second mode of operation is achieved by specifying the C Toolkit BLAST command line application invocation and appending the `--print_only` command line option as follows:

```
$ ./legacy_blast.pl megablast -i query.fsa -d nt -o mb.out --print_only
/opt/ncbi/blast/bin/blastn -query query.fsa -db "nt" -out mb.out
$
```

Exit codes

All BLAST+ applications have consistent exit codes to signify the exit status of the application. The possible exit codes along with their meaning are detailed in the table below:

Exit Code	Meaning
0	Success
1	Error in query sequence(s) or BLAST options
2	Error in BLAST database
3	Error in BLAST engine
4	Out of memory
5	Network error connecting to NCBI to fetch sequence data
6	Error creating output files
255	Unknown error

In the case of BLAST+ database applications, the possible exit codes are 0 (indicating success) and 1 (indicating failure).

Options for the command-line applications.

This appendix consists of several tables that list option names, types, default values, and a short description of the option. These tables were first published as an appendix to an article in BMC Bioinformatics ([BLAST+: architecture and applications](#)). They have been updated for this manual.

Table C1: Options common to all BLAST+ search applications. An option of type “flag” takes no argument, but if present is true. Some options are valid only for a local search (“remote” option not used), others are valid only for a remote search (“remote” option used).

<i>option</i>	type	default value	description and notes
db	string	none	BLAST database name.
query	string	stdin	Query file name.
query_loc	string	none	Location on the query sequence (Format: start-stop)
out	string	stdout	Output file name
evaluate	real	10.0	Expect value (E) for saving hits
subject	string	none	File with subject sequence(s) to search.

Table C1 continued from previous page.

<i>option</i>	<i>type</i>	<i>default value</i>	<i>description and notes</i>
subject_loc	string	none	Location on the subject sequence (Format: start-stop).
show_gis	flag	N/A	Show NCBI GIs in report.
num_descriptions	integer	500	Show one-line descriptions for this number of database sequences.
num_alignments	integer	250	Show alignments for this number of database sequences.
max_target_seqs	integer	500	Number of aligned sequences to keep. Use with report formats that do not have separate definition line and alignment sections such as tabular (all outfmt > 4). Not compatible with num_descriptions or num_alignments. Ties are broken by order of sequences in the database.
max_hsps	integer	none	Maximum number of HSPs (alignments) to keep for any single query-subject pair. The HSPs shown will be the best as judged by expect value. This number should be an integer that is one or greater. If this option is not set, BLAST shows all HSPs meeting the expect value criteria. Setting it to one will show only the best HSP for every query-subject pair
html	flag	N/A	Produce HTML output
gilst	string	none	Restrict search of database to GI's listed in this file. Local searches only.
negative_gilst	string	none	Restrict search of database to everything except the GI's listed in this file. Local searches only.
entrez_query	string	none	Restrict search with the given Entrez query. Remote searches only.
culling_limit	integer	none	Delete a hit that is enveloped by at least this many higher-scoring hits.
best_hit_overhang	real	none	Best Hit algorithm overhang value (recommended value: 0.1)
best_hit_score_edge	real	none	Best Hit algorithm score edge value (recommended value: 0.1)
dbsize	integer	none	Effective size of the database
searchsp	integer	none	Effective length of the search space
import_search_strategy	string	none	Search strategy file to read.

Table C1 continued from previous page.

option	type	default value	description and notes
export_search_strategy	string	none	Record search strategy to this file.
parse_deflines	flag	N/A	Parse query and subject bar delimited sequence identifiers (e.g., gi 129295).
num_threads	integer	1	Number of threads (CPUs) to use in blast search.
remote	flag	N/A	Execute search on NCBI servers?
outfmt	string	0	<p>alignment view options:</p> <p>0 = pairwise,</p> <p>1 = query-anchored showing identities,</p> <p>2 = query-anchored no identities,</p> <p>3 = flat query-anchored, show identities,</p> <p>4 = flat query-anchored, no identities,</p> <p>5 = XML Blast output,</p> <p>6 = tabular,</p> <p>7 = tabular with comment lines,</p> <p>8 = Text ASN.1,</p> <p>9 = Binary ASN.1</p> <p>10 = Comma-separated values</p> <p>11 = BLAST archive format (ASN.1)</p> <p>12 = Seqalign (JSON),</p> <p>13 = Multiple-file BLAST JSON,</p> <p>14 = Multiple-file BLAST XML2,</p> <p>15 = Single-file BLAST JSON,</p> <p>16 = Single-file BLAST XML2,</p> <p>17 = Sequence Alignment/Map (SAM),</p> <p>18 = Organism Report</p> <p>Options 6, 7, and 10 can be additionally configured to produce a custom format specified by space delimited format specifiers.</p> <p>The supported format specifiers are:</p> <p>qseqid means Query Seq-id</p> <p>qgi means Query GI</p> <p>qacc means Query accession</p> <p>sseqid means Subject Seq-id</p> <p>sallseqid means All subject Seq-id(s), separated by a ','</p>

Table C1 continued from previous page.

option	type	default value	description and notes
			sgi means Subject GI
			sallgi means All subject GIs
			sacc means Subject accession
			sallacc means All subject accessions
			qstart means Start of alignment in query
			qend means End of alignment in query
			sstart means Start of alignment in subject
			send means End of alignment in subject
			qseq means Aligned part of query sequence
			sseq means Aligned part of subject sequence
			evalvalue means Expect value
			bitscore means Bit score
			score means Raw score
			length means Alignment length
			pident means Percentage of identical matches
			nident means Number of identical matches
			mismatch means Number of mismatches
			positive means Number of positive-scoring matches
			gapopen means Number of gap openings
			gaps means Total number of gap
			ppos means Percentage of positive-scoring matches
			frames means Query and subject frames separated by a '/'
			qframe means Query frame
			sframe means Subject frame
			btop means Blast traceback operations (BTOP)
			staxids means unique Subject Taxonomy ID(s), separated by a ';' (in numerical order)
			sscinames means unique Subject Scientific Name(s), separated by a ';' (in alphabetical order)
			scomnames means unique Subject Common Name(s), separated by a ';' (in alphabetical order)
			sblastnames means unique Subject Blast Name(s), separated by a ';' (in alphabetical order)
			sskingdoms means unique Subject Super Kingdom(s), separated by a ';' (in alphabetical order)
			stitle means Subject Title
			salltitles means All Subject Title(s), separated by a '<>'

Table C1 continued from previous page.

option	type	default value	description and notes
			<p>sstrand means Subject Strand</p> <p>qcovs means Query Coverage Per Subject (for all HSPs)</p> <p>qcovhsp means Query Coverage Per HSP</p> <p>qcovus is a measure of Query Coverage that counts a position in a subject sequence for this measure only once. The second time the position is aligned to the query is not counted towards this measure.</p> <p>When not provided, the default value is:</p> <p>'qseqid sseqid pident length mismatch gapopen qstart qend sstart send eval evalue bitscore', which is equivalent to the keyword 'std'</p>
mt_mode	integer	0	<p>Values can be 0 or 1.</p> <p>Value of 0 indicates that BLAST should multi-thread by having each thread work on a part of the database. This is appropriate for a small number of queries and a larger database (e.g., larger than Swissprot). Value 1 indicates that each thread will take a batch of queries and process them independently. This works well for large query sets (10k residues per thread for BLASTP and 2 million bases per thread for BLASTN) and smaller databases (e.g., Swissprot).</p>

Table C2: blastn application options. The blastn application searches a nucleotide query against nucleotide subject sequences or a nucleotide database. An option of type “flag” takes no arguments, but if present the argument is true. Four different tasks are supported: 1.) “megablast”, for very similar sequences (e.g, sequencing errors), 2.) “dc-megablast”, typically used for inter-species comparisons, 3.) “blastn”, the traditional program used for inter-species comparisons, 4.) “blastn-short”, optimized for sequences less than 30 nucleotides.

option	task(s)	type	default value	description and notes
word_size	megablast	integer	28	Length of initial exact match.
word_size	dc-megablast	integer	11	Number of matching nucleotides in initial match. dc-megablast allows non-consecutive letters to match.
word_size	blastn	integer	11	Length of initial exact match.
word_size	blastn-short	integer	7	Length of initial exact match.
gapopen	megablast	integer	0	Cost to open a gap. See appendix “BLASTN reward/penalty values”.
gapextend	megablast	integer	none	Cost to extend a gap. This default is a function of reward/penalty value. See appendix “BLASTN reward/penalty values”.

Table C2 continued from previous page.

option	task(s)	type	default value	description and notes
gapopen	blastn, blastn-short, dc-megablast	integer	5	Cost to open a gap. See appendix “BLASTN reward/penalty values”.
gapextend	blastn, blastn-short, dc-megablast	integer	2	Cost to extend a gap. See appendix “BLASTN reward/penalty values”.
reward	megablast	integer	1	Reward for a nucleotide match.
penalty	megablast	integer	-2	Penalty for a nucleotide mismatch.
reward	blastn, dc-megablast	integer	2	Reward for a nucleotide match.
penalty	blastn, dc-megablast	integer	-3	Penalty for a nucleotide mismatch.
reward	blastn-short	integer	1	Reward for a nucleotide match.
penalty	blastn-short	integer	-3	Penalty for a nucleotide mismatch.
strand	all	string	both	Query strand(s) to search against database/subject. Choice of both, minus, or plus.
dust	all	string	20 64 1	Filter query sequence with dust.
filtering_db	all	string	none	Mask query using the sequences in this database.
window_masker_taxid	all	integer	none	Enable WindowMasker filtering using a Taxonomic ID.
window_masker_db	all	string	none	Enable WindowMasker filtering using this file.
soft_masking	all	boolean	true	Apply filtering locations as soft masks (i.e., only for finding initial matches).
lcase_masking	all	flag	N/A	Use lower case filtering in query and subject sequence(s).
db_soft_mask	all	integer	none	Filtering algorithm ID to apply to the BLAST database as soft mask (i.e., only for finding initial matches).
db_hard_mask	all	integer	none	Filtering algorithm ID to apply to the BLAST database as hard mask (i.e., sequence is masked for all phases of search).

Table C2 continued from previous page.

option	task(s)	type	default value	description and notes
perc_identity	all	integer	0	Percent identity cutoff.
template_type	dc-megablast	string	coding	Discontiguous MegaBLAST template type. Allowed values are coding, optimal and coding_and_optimal.
template_length	dc-megablast	integer	18	Discontiguous MegaBLAST template length.
use_index	megablast	boolean	false	Use MegaBLAST database index. Indices may be created with the makemindex application.
index_name	megablast	string	none	MegaBLAST database index name.
xdrop_ungap	all	real	20	Heuristic value (in bits) for ungapped extensions.
xdrop_gap	all	real	30	Heuristic value (in bits) for preliminary gapped extensions.
xdrop_gap_final	all	real	100	Heuristic value (in bits) for final gapped alignment.
no_greedy	megablast	flag	N/A	Use non-greedy dynamic programming extension.
min_raw_gapped_score	all	integer	none	Minimum raw gapped score to keep an alignment in the preliminary gapped and trace-back stages. Normally set based upon expect value.
ungapped	all	flag	N/A	Perform ungapped alignment.
window_size	dc-megablast	integer	40	Multiple hits window size, use 0 to specify 1-hit algorithm

Table C3: blastp application options. The blastp application searches a protein sequence against protein subject sequences or a protein database. An option of type “flag” takes no arguments, but if present the argument is true. Three different tasks are supported: 1.) “blastp”, for standard protein-protein comparisons, 2.) “blastp-short”, optimized for query sequences shorter than 30 residues, and 3.) “blastp-fast”, a faster version that uses a larger word-size per <https://www.ncbi.nlm.nih.gov/pubmed/17921491>. This table reflects the 2.2.27 BLAST+ release.

option	task	type	default value	description and notes
word_size	blastp	integer	3	Word size of initial match. Valid word sizes are 2-7.
word_size	blastp-short	integer	2	Word size of initial match.
word size	blastp-fast	Integer	6	Word size of initial match

Table C3 continued from previous page.

option	task	type	default value	description and notes
gapopen	blastp	integer	11	Cost to open a gap.
gapextend	blastp	integer	1	Cost to extend a gap.
gapopen	blastp-short	integer	9	Cost to open a gap.
gapextend	blastp-short	integer	1	Cost to extend a gap.
matrix	blastp	string	BLOSUM62	Scoring matrix name.
matrix	blastp-short	string	PAM30	Scoring matrix name.
threshold	blastp	integer	11	Minimum score to add a word to the BLAST lookup table.
threshold	blastp-short	integer	16	Minimum score to add a word to the BLAST lookup table.
Threshold	Blastp-fast	Integer	21	Minimum score to add a word to the BLAST lookup table.
comp_based_stats	Blastp and blastp-fast	string	2	Use composition-based statistics: D or d: default (equivalent to 2) 0 or F or f: no composition-based statistics 1: Composition-based statistics as in NAR 29:2994-3005, 2001 2 or T or t : Composition-based score adjustment as in Bioinformatics 21:902-911, 2005, conditioned on sequence properties 3: Composition-based score adjustment as in Bioinformatics 21:902-911, 2005, unconditionally
comp_based_stats	blastp-short	string	0	Use composition-based statistics : D or d: default (equivalent to 2) 0 or F or f: no composition-based statistics 1: Composition-based statistics as in NAR 29:2994-3005, 2001 2 or T or t : Composition-based score adjustment as in Bioinformatics 21:902-911, 2005, conditioned on sequence properties 3: Composition-based score adjustment as in Bioinformatics 21:902-911, 2005, unconditionally

Table C3 continued from previous page.

option	task	type	default value	description and notes
seg	all	string	no	Filter query sequence with SEG (Format: 'yes', 'window locut hicut', or 'no' to disable).
soft_masking	blastp	boolean	false	Apply filtering locations as soft masks (i.e., only for finding initial matches).
lcase_masking	all	flag	N/A	Use lower case filtering in query and subject sequence(s).
db_soft_mask	all	integer	none	Filtering algorithm ID to apply to the BLAST database as soft mask (i.e., only for finding initial matches).
db_hard_mask	all	integer	none	Filtering algorithm ID to apply to the BLAST database as hard mask (i.e., sequence is masked for all phases of search).
xdrop_gap_final	all	real	25	Heuristic value (in bits) for final gapped alignment/
window_size	Blastp and blastp-fast	integer	40	Multiple hits window size, use 0 to specify 1-hit algorithm.
window_size	blastp-short	integer	15	Multiple hits window size, use 0 to specify 1-hit algorithm.
use_sw_tback	all	flag	N/A	Compute locally optimal Smith-Waterman alignments?

Table C4: blastx application options. The blastx application translates a nucleotide query and searches it against protein subject sequences or a protein database. Two different tasks are supported: 1.) “blastx” for standard translated nucleotide-protein comparison and 2.) “blastx-fast”, a faster version that uses a larger word-size based on <https://www.ncbi.nlm.nih.gov/pubmed/17921491>.

option	task	type	default value	description and notes
word_size	Blastx	integer	3	Word size for initial match. Valid word sizes are 2-7.
word_size	Blastx-fast	Integer	6	Word size for initial match.
gapopen	All	integer	11	Cost to open a gap.
gapextend	All	integer	1	Cost to extend a gap.
matrix	All	string	BLOSUM62	Scoring matrix name.
threshold	Blastx	integer	12	Minimum score to add a word to the BLAST lookup table.

Table C4 continued from previous page.

option	task	type	default value	description and notes
threshold	Blastx-fast	Integer	21	Minimum score to add a word to the BLAST lookup table.
seg	All	string	12 2.2 2.5	Filter query sequence with SEG (Format: 'yes', 'window locut hicut', or 'no' to disable).
soft_masking	all	boolean	false	Apply filtering locations as soft masks (i.e., only for finding initial matches).
lcase_masking	all	flag	N/A	Use lower case filtering in query and subject sequence(s).
db_soft_mask	all	integer	none	Filtering algorithm ID to apply to the BLAST database as soft mask (i.e., only for finding initial matches).
db_hard_mask	all	integer	none	Filtering algorithm ID to apply to the BLAST database as hard mask (i.e., sequence is masked for all phases of search).
xdrop_gap_final	all	real	25	Heuristic value (in bits) for final gapped alignment.
window_size	all	integer	40	Multiple hits window size, use 0 to specify 1-hit algorithm.
strand	all	string	both	Query strand(s) to search against database/subject. Choice of both, minus, or plus.
query_genetic_code	all	integer	1	Genetic code to translate query, see ftp://ftp.ncbi.nih.gov/entrez/misc/data/gc.prt
max_intron_length	all	integer	0	Length of the largest intron allowed in a translated nucleotide sequence when linking multiple distinct alignments (a negative value disables linking).
comp_based_stats	all	integer	2	Use composition-based statistics for blastx: D or d: default (equivalent to 2) 0 or F or f: no composition-based statistics 1: Composition-based statistics as in NAR 29:2994-3005, 2001 2 or T or t : Composition-based score adjustment as in Bioinformatics 21:902-911, 2005, conditioned on sequence properties 3: Composition-based score adjustment as in Bioinformatics 21:902-911, 2005, unconditionally Default = '2'

Table C5: tblastn application options. The tblastn application searches a protein query against nucleotide subject sequences or a nucleotide database translated at search time. Two different tasks are supported: 1.) “tblastn” for a standard protein-translated nucleotide comparison and 2.) “tblastn-fast” for a faster version with a larger word-size based on <https://www.ncbi.nlm.nih.gov/pubmed/17921491>.

option	task	type	default value	description and notes
word_size	tblastn	integer	3	Word size for initial match. Valid word sizes are 2-7.
Word size	tblastn-fast	Integer	6	Word size for initial match.
gapopen	All	integer	11	Cost to open a gap.
gapextend	All	integer	1	Cost to extend a gap.
matrix	All	string	BLOSUM62	Scoring matrix name.
threshold	tblastn	integer	13	Minimum score to add a word to the BLAST lookup table.
threshold	tblastn-fast	Integer	21	Minimum score to add a word to the BLAST lookup table.
seg	All	string	12 2.2 2.5	Filter query sequence with SEG (Format: 'yes', 'window locut hicut', or 'no' to disable).
soft_masking	All	boolean	false	Apply filtering locations as soft masks (i.e., only for finding initial matches).
lcase_masking	All	flag	N/A	Use lower case filtering in query and subject sequence(s).
db_soft_mask	All	integer	none	Filtering algorithm ID to apply to the BLAST database as soft mask (i.e., only for finding initial matches).
db_hard_mask	All	integer	none	Filtering algorithm ID to apply to the BLAST database as hard mask (i.e., sequence is masked for all phases of search).
xdrop_gap_final	All	real	25	Heuristic value (in bits) for final gapped alignment.
window_size	All	integer	40	Multiple hits window size, use 0 to specify 1-hit algorithm.
db_gen_code	All	integer	1	Genetic code to translate subject sequences, see ftp://ftp.ncbi.nih.gov/entrez/misc/data/gc.prt
max_intron_length	All	integer	0	Length of the largest intron allowed in a translated nucleotide sequence when linking multiple distinct alignments (a negative value disables linking).

Table C5 continued from previous page.

option	task	type	default value	description and notes
comp_based_stats	all	string	2	Use composition-based statistics for tblastn: D or d: default (equivalent to 2) 0 or F or f: no composition-based statistics 1: Composition-based statistics as in NAR 29:2994-3005, 2001 2 or T or t : Composition-based score adjustment as in Bioinformatics 21:902-911, 2005, conditioned on sequence properties 3: Composition-based score adjustment as in Bioinformatics 21:902-911, 2005, unconditionally Default = `2'

Table C6: tblastx application options. The tblastx application searches a translated nucleotide query against translated nucleotide subject sequences or a translated nucleotide database. An option of type “flag” takes no arguments, but if present the argument is true. This table reflects the 2.2.27 BLAST+ release. Only ungapped searches are supported for tblastx.

option	type	default value	description and notes
word_size	integer	3	Word size for initial match.
matrix	string	BLOSUM62	Scoring matrix name.
threshold	integer	13	Minimum word score to add the word to the BLAST lookup table.
seg	string	12 2.2 2.5	Filter query sequence with SEG (Format: 'yes', 'window locut hicut', or 'no' to disable).
soft_masking	boolean	false	Apply filtering locations as soft masks (i.e., only for finding initial matches).
lcase_masking	flag	N/A	Use lower case filtering in query and subject sequence(s).
db_soft_mask	integer	none	Filtering algorithm ID to apply to the BLAST database as soft mask (i.e., only for finding initial matches).
db_hard_mask	integer	none	Filtering algorithm ID to apply to the BLAST database as hard mask (i.e., sequence is masked for all phases of search).
strand	string	both	Query strand(s) to search against database subject sequences. Choice of both, minus, or plus.
query_genetic_code	integer	1	Genetic code to translate query, see ftp://ftp.ncbi.nih.gov/entrez/misc/data/gc.prt

Table C6 continued from previous page.

option	type	default value	description and notes
db_gen_code	integer	1	Genetic code to translate subject sequences, see ftp://ftp.ncbi.nih.gov/entrez/misc/data/gc.prt
max_intron_length	integer	0	Length of the largest intron allowed in a translated nucleotide sequence when linking multiple distinct alignments (a negative value disables linking)

Table C7: rpsblast application options. The rpsblast application searches a protein query against the conserved domain database (CDD), which is a set of protein profiles. Many of the common options such as matrix or word threshold are set when the CDD is built and cannot be changed by the rpsblast application. A search ready CDD can be downloaded from <ftp://ftp.ncbi.nih.gov/pub/mmdb/cdd/>

Option	Type	Default value	Description and notes
window_size	integer	40	Multiple hits window size, use 0 to specify 1-hit algorithm.
xdrop_ungap	real	15	Heuristic value (in bits) for ungapped extensions
xdrop_gap	real	25	Heuristic value (in bits) for preliminary gapped extensions.
xdrop_gap_final	real	40	Heuristic value (in bits) for final gapped alignment.
seg	string	12 2.2 2.5	Filter query sequence with SEG (Format: 'yes', 'window locut hicut', or 'no' to disable).
soft_masking	boolean	false	Apply filtering locations as soft masks (i.e., only for finding initial matches).
mt_mode	integer	0	Set to 1 if a large number of queries are to be searched and you wish to use multiple threads, as specified by the num_threads argument.
comp_based_stats	integer	2	Use composition-based statistics for rpsblast: D or d: default (equivalent to 2) 0 or F or f: no composition-based statistics 1: Composition-based statistics as in NAR 29:2994-3005, 2001 2 or T or t: Composition-based score adjustment as in Bioinformatics 21:902-911, 2005, conditioned on sequence properties 3: Composition-based score adjustment as in Bioinformatics 21:902-911, 2005, unconditionally Default = '2'

Table C8: Makeblastdb application options. This application builds a BLAST database. An option of type “flag” takes no arguments, but if present the argument is true. Starting with the 2.10.0 release, makeblastdb produces version 5 databases by default, which uses LMDB. LMDB requires virtual memory (at least 600 GB, but 800 GB is recommended) to build an index. If makeblastdb cannot access enough virtual memory, it will produce a message containing the string “mdb_env_open”. Virtual memory is just that (virtual) and doesn't depend on the hardware in your system. In general, we recommend that BLAST users simply set the virtual memory to unlimited. The other alternative is to use an environment variable (BLASTDB_LMDB_MAP_SIZE) to set the required virtual memory lower, but this runs the risk of LMDB not being able to complete indexing the database. For a smaller database (tens of millions of letters) it may be possible to use a value of 100 million.

option	type	default value	Description and notes
in	string	stdin	Input file/database name

Table C8 continued from previous page.

option	type	default value	Description and notes
input_type	string	fasta	Input file type, it may be any of the following: fasta: for FASTA file(s) blastdb: for BLAST database(s) asn1_txt: for Seq-entries in text ASN.1 format asn1_bin: for Seq-entries in binary ASN.1 format
dbtype	string	prot	Molecule type of input, values can be nucl or prot.
title	string	none	Title for BLAST database. If not set, the input file name will be used.
parse_seqids	flag	N/A	Parse bar delimited sequence identifiers (e.g., gi 129295) in FASTA input.
hash_index	flag	N/A	Create index of sequence hash values.
mask_data	string	none	Comma-separated list of input files containing masking data as produced by NCBI masking applications (e.g. dustmasker, segmasker, windowmasker).
out	string	input file name	Name of BLAST database to be created. Input file name is used if none provided. This field is required if input consists of multiple files.
max_file_size	string	1GB	Maximum file size to use for BLAST database. 4GB is the maximum supported by the database structure.
blastdb_version	integer	5	Version 5 (taxonomy aware) is the default starting with the 2.10.0 release. Value must be 4 or 5.
taxid	integer	none	Taxonomy ID to assign to all sequences.
taxid_map	string	none	File with two columns mapping sequence ID to the taxonomy ID. The first column is the sequence ID represented as one of: <ol style="list-style-type: none">1. fasta with accessions (e.g., emb X17276.1)2. fasta with GI (e.g., gi 4)3. GI as a bare number (e.g., 4)4. A local ID. The local ID must be prefixed with "lcl" (e.g., lcl 4). The second column should be the NCBI taxonomy ID (e.g., 9606 for human).
logfile	string	none	Program log file (default is stderr).

Table C9: Makeprofiledb application options. This application builds an RPS-BLAST database. An option of type “flag” takes no arguments, but if present the argument is true. COBALT (a multiple sequence alignment program) and DELTA-BLAST both use RPS-

BLAST searches as part of their processing but use specialized versions of the database. This application can build databases for COBALT, DELTA-BLAST, and a standard RPS-BLAST search. The “dbtype” option (see entry in table) determines which flavor of the database is built.

option	type	default value	Description and notes
in	string	stdin	Input file that contains a list of scoremat files (delimited by space, tab, or newline)
binary	flag	N/A	The scoremat files are binary ASN.1
title	string	none	Title for RPS-BLAST database. If not set, the input file name will be used.
threshold	real	9.82	Threshold for RPSBLAST lookup table.
out	string	input file name	Name of BLAST database to be created. Input file name is used if none provided.
max_file_size	string	1GB	Maximum file size to use for BLAST database.
dbtype	string	rps	Specifies use for RPSBLAST db. One of rps, cobalt, or delta.
index	flag	N/A	Creates index files.
gapopen	integer	none	Cost to open a gap. Used only if scoremat files do not contain PSSM scores, otherwise ignored.
gapextend	integer	none	Cost to extend a gap by one residue. Used only if scoremat files do not contain PSSM scores, otherwise ignored.
scale	real	100	PSSM scale factor.
matrix	string	BLOSUM62	Matrix to use in constructing PSSM. One of BLOSUM45, BLOSUM50, BLOSUM62, BLOSUM80, BLOSUM90, PAM250, PAM30 or PAM70. Used only if scoremat files do not contain PSSM scores, otherwise ignored.
obsr_threshold	real	6	Exclude domains with maximum number of independent observations below this value (for use in DELTA-BLAST searches).
exclude_invalid	real	true	Exclude domains that do not pass validation test (for use in DELTA-BLAST searches).
max_smp_vol	integer	2500	Maximum number of SMP files per DB volume. Increasing this number will decrease the number of BLAST database volumes produced.
taxid	integer	none	Taxonomy ID to assign to all sequences.

Table C9 continued from previous page.

option	type	default value	Description and notes
taxid_map	string	none	<p>File with two columns mapping sequence ID to the taxonomy ID. The first column is the sequence ID represented as one of:</p> <ol style="list-style-type: none"> 1. fasta with accessions (e.g., emb X17276.1) 2. fasta with GI (e.g., gi 4) 3. GI as a bare number (e.g., 4) 4. A local ID. The local ID must be prefixed with "lcl" (e.g., lcl 4). <p>The second column should be the NCBI taxonomy ID (e.g., 9606 for human).</p>
logfile	string	none	Program log file (default is stderr).

Table C10: Blastdbcmd application options. This application reads a BLAST database and produces reports.

option	type	default value	description and notes
db	string	nr	BLAST database name.
dbtype	string	guess	Molecule type stored in BLAST database, one of nucl, prot, or guess.
entry	string	none	Comma-delimited search string(s) of sequence identifiers: e.g.: 555, AC147927, 'gnl dbname tag', or 'all' to select all sequences in the database
entry_batch	string	none	Input file for batch processing. The format requires one entry per line; each line should begin with the sequence ID followed by any of the following optional specifiers (in any order): range (format: 'from-to', inclusive in 1-offsets), strand ('plus' or 'minus'), or masking algorithm ID (integer value representing the available masking algorithm). Omitting the ending range (e.g.: '10-') is supported, but there should not be any spaces around the '-':
pig	integer	none	PIG (protein identity group) to retrieve.
info	flag	N/A	Print BLAST database information.
range	string	none	Range of sequence to extract (Format: start-stop).
strand	string	plus	Strand of nucleotide sequence to extract. Choice of plus or minus.
mask_sequence_with	string	none	Produce lower-case masked FASTA using the algorithm IDs specified.
out	string	stdout	Output file name.
outfmt	string	%f	<p>Output format, where the available format specifiers are:</p> <p>%f means sequence in FASTA format</p>

Table C10 continued from previous page.

option	type	default value	description and notes
			%s means sequence data (without define) %a means accession %g means gi %o means ordinal id (OID) %t means sequence title %l means sequence length %T means taxid %L means common taxonomic name %S means scientific name %P means PIG %mX means sequence masking data, where X is an optional comma-separated list of integers to specify the algorithm ID(s) to display (or all masks if absent or invalid specification). Masking data will be displayed as a series of 'N-M' values separated by ';' or the word 'none' if none are available. For every format except '%f', each line of output will correspond to a sequence.
target_only	flag	N/A	Definition line should contain target GI only.
get_dups	flag	N/A	Retrieve duplicate accessions.
line_length	integer	80	Line length for output.
ctrl_a	flag	N/A	Use Ctrl-A as the non-redundant definition line separator.

Table C11: Makemindex application options. The indexed databases created by makemindex are used by production MegaBLAST software and by a new srsearch utility designed to quickly search for nearly exact matches (up to one mismatch) of short queries against a genomic database. When a FASTA formatted file is used as the input, then masking by lower case letters is incorporated in the index. Makemindex can currently build two types of indices, called “old style” and “new style” indexing. The NCBI offers full support for the new style and has deprecated the old style. A MegaBLAST search with a new style index requires that both the index and the corresponding BLAST database be present. The index structure is described in [PMID:18567917](#). Please cite this paper in any publication that uses makemindex.

option	type	default value	Description and notes
input	string	stdin	Input file name or BLAST database name, depending on the value of the iformat parameter. For FASTA formatted input, this parameter is optional and defaults to the program's standard input stream.
output	string	none	The resulting index name. The index itself can consist of multiple files, called volumes, called <index_name>.00.idx, <index_name>.01.idx,... This option should not be used with new style indices.

Table C11 continued from previous page.

option	type	default value	Description and notes
ifformat	string	fasta	The input format selector. Possible values are 'fasta' and 'blastdb'.
old_style_index	boolean	false	The old_style_index is no longer supported. If set to 'false' the new style index is created. New style indices require a BLAST database as input (use -ifformat blastdb), which can be downloaded from the NCBI FTP site or created with makeblastdb. The option -output is ignored for a new style index. New style indices are always created at the same location as the corresponding BLAST database.
db_mask	integer	None	Exclude masked regions of BLAST db from the index. Use makeblastdb to discover the algorithm ID to be used as input for this argument.
legacy	boolean	true	This is a compatibility feature to support current production MegaBLAST. If true, then -stride, -nmer, and -ws_hint are ignored. The legacy format must be used for BLAST.
nmer	integer	12	N-mer size to use. Ignored if -legacy is specified
ws_hint	integer	28	This is an optimization hint for makembindindex that indicates an expected minimum match size in searches that use the index. If n is the value of -nmer parameter and s is the value of -stride parameter, then the value of -ws_hint must be at least $n + s - 1$.
stride	integer	5	makembindindex will index every stride-th N-mer of the database.
volsize	integer	1536	Target index volume size in megabytes.

BLASTN reward/penalty values

BLASTN uses a simple approach to score alignments, with identically matching bases assigned a reward and mismatching bases assigned a penalty. It is important to choose reward/penalty values appropriate to the sequences being aligned with the (absolute) reward/penalty ratio increasing for more divergent sequences. A ratio of 0.33 (1/-3) is appropriate for sequences that are about 99% conserved; a ratio of 0.5 (1/-2) is best for sequences that are 95% conserved; a ratio of about one (1/-1) is best for sequences that are 75% conserved [2].

For each reward/penalty pair, a number of different gap costs are supported. A gap cost includes a value to open the gap and a value to extend the gap by a base. Following the convention of the command-line applications, these costs are listed as positive numbers here. MegaBLAST uses a specialized algorithm to calculate the default gap costs for a reward/penalty pair that is described in [PMID:10890397](#). Briefly, the default megaBLAST cost to open a gap is zero and the cost to extend a gap two letters is given by the absolute value of two mismatches minus one match. For example, given a reward of 1 and penalty of -5, the cost to extend a gap by one letter is 5.5. The default gap costs for other tasks supported by the blastn application is 5 to open a gap and 2 to extend one base.

Table D1 presents the supported reward/penalty values and gap costs.

Table D1: Supported reward/penalty values and gap costs for the blastn application. The left-most column presents the supported reward/penalty values. The middle column presents pairs of numbers for the cost to open and extend a gap for each reward/penalty

value. Blastn also supports gap costs more stringent than those listed (e.g., for reward/penalty of 1/-3 gap costs of 5/2 or 500/2 are supported). The reward/penalty values are ordered from most to least stringent, with the more stringent values better suited for alignments with high sequence identity. The default megaBLAST gap costs are shown in the right-most column. Accurate statistics for these default megaBLAST gap costs can only be calculated for the most stringent reward/penalty values, but the values listed in the middle column can always be used.

reward/penalty	gap costs (open/extend)	default MegaBLAST gap costs (open/extend)
1/-5	3/3	0/5.5
1/-4	1/2, 0/2, 2/1, 1/1	0/4.5
2/-7	2/4, 0/4, 4/2, 2/2	0/8
1/-3	2/2, 1/2, 0/2, 2/1, 1/1	0/3.5
2/-5	2/4, 0/4, 4/2, 2/2	0/6
1/-2	2/2, 1/2, 0/2, 3/1, 2/1, 1/1	0/2.5
2/-3	4/4, 2/4, 0/4, 3/3, 6/2, 5/2, 4/2, 2/2	0/4
3/-4	6/3, 5/3, 4/3, 6/2, 5/2, 4/2	N/A
4/-5	6/5, 5/5, 4/5, 3/5	N/A
1/-1	3/2, 2/2, 1/2, 0/2, 4/1, 3/1, 2/1	N/A
3/-2	5/5	N/A
5/-4	10/6, 8/6	N/A

BLAST Substitution Matrices

BLAST uses a substitution matrix for any program that aligns residues. The program may align residues because both the query and database consist of proteins (e.g. BLASTP) or the program may align DNA translated to protein with protein (e.g. BLASTX). A key element in evaluating the quality of a pairwise sequence alignment is the "substitution matrix", which assigns a score for aligning any possible pair of residues. The theory of amino acid substitution matrices is described in [1], and applied to DNA sequence comparison in [2]. In general, different substitution matrices are tailored to detecting similarities among sequences that are diverged by differing degrees [1-3]. A single matrix may nevertheless be reasonably efficient over a relatively broad range of evolutionary change [1-3]. Experimentation has shown that the BLOSUM-62 matrix [4] is among the best for detecting most weak protein similarities. For particularly long and weak alignments, the BLOSUM-45 matrix may prove superior. A detailed statistical theory for gapped alignments has not been developed, and the best gap costs to use with a given substitution matrix are determined empirically. Short alignments need to be relatively strong (i.e. have a higher percentage of matching residues) to rise above background noise. Such short but strong alignments are more easily detected using a matrix with a higher "relative entropy" [1] than that of BLOSUM-62. In particular, short query sequences can only produce short alignments, and therefore database searches with short queries should use an appropriately tailored matrix. The BLOSUM series does not include any matrices with relative entropies suitable for the shortest queries, so the older PAM matrices [5,6] may be used instead. For proteins, a provisional table of recommended substitution matrices and gap costs for various query lengths is:

Query Length	Substitution Matrix	Gap Costs
<35	PAM-30	(9, 1)
35-50	PAM-70	(10, 1)
50-85	BLOSUM-80	(10, 1)
>85	BLOSUM-62	(11, 1)

Gap Costs

The raw score of an alignment is the sum of the scores for aligning pairs of residues and the scores for gaps. Gapped BLAST and PSI-BLAST use "affine gap costs" which charge the score $-a$ for the existence of a gap, and the score $-b$ for each residue in the gap. Thus a gap of k residues receives a total score of $-(a+bk)$; specifically, a gap of length 1 receives the score $-(a+b)$.

Lambda Ratio

To convert a raw score S into a normalized score S' expressed in bits, one uses the formula $S' = (\lambda S - \ln K) / (\ln 2)$, where λ and K are parameters dependent upon the scoring system (substitution matrix and gap costs) employed [7-9]. For determining S' , the more important of these parameters is λ . The "lambda ratio" quoted here is the ratio of the λ for the given scoring system to that for one using the same substitution scores, but with infinite gap costs [8]. This ratio indicates what proportion of information in an ungapped alignment must be sacrificed in the hope of improving its score through extension using gaps. We have found empirically that the most effective gap costs tend to be those with lambda ratios in the range 0.8 to 0.9.

Outline of the BLAST process

Introduction

BLAST performs several steps as it searches through a database and winnows the matches, finding the most significant matches that it finally presents to the user. The initial step in this process is the fastest and examines every sequence. Each successive step takes longer but examines fewer sequences. The outline below provides details on the process and a figure provides a visual representation. This outline applies only to gapped BLAST. A letter and number in the figure (e.g., C3) refers to a step in the outline. BLAST is described in greater detail in <https://www.ncbi.nlm.nih.gov/pubmed/9254694>.

Outline

- A. Read in user query and preprocess (mask for low-complexity, etc.)
- B. Read user options and set parameters for the search. This includes examining how many matches (database sequences) the user wants returned and the expect value. If the user wants N database sequences returned and sets an expect value of E , then:
 1. For Composition-based statistics (CBS), set an (internal) maximum limit of $N_i = 2 * N + 50$ database sequences and an internal expect value of $E_i = 5 * E$. CBS applies only to protein-protein comparisons and is available for BLASTP, BLASTX, TBLASTN, RPSBLAST, and RPSTBLASTN.
 2. Otherwise, set a maximum limit of $N_i = \text{MAX}(\text{MIN}(2 * N, N + 50), 10)$ database sequences.
- C. Loop over every sequence in the database, performing the following actions:
 1. Scan for initial matching word hits. If an initial hit is found, then move on to step 2, otherwise move on to next sequence. Example initial matching word hits are:
 - a. 11 bases exact match for BLASTN.
 - b. 28 bases exact match for MegaBLAST
 - c. 3 residue match with score above threshold for BLAST[PX]/TBLASTN (default requires 2 word hits on a diagonal)
 - d. 6 residue match with score above threshold for BLAST[PX]/TBLASTN for fast task “blastp-fast” etc. (default requires 2 on diagonal)
 2. Perform a gap free extension based on the initial word hits. If this extension has a score above S_g (set so that about one in 50 database sequences pass) then move on to step 3. Otherwise move on to next sequence.
 3. Perform a gapped extension based on the gap free extension. This gapped extension does not collect traceback information, but only the extent of the alignment and the resulting score (making it fast). This gapped extension uses a modified dynamic programming algorithm that only explores a limited space based on a parameter called X_g . If the resulting alignment passes the score cutoff (determined by expect value) move on to next step, otherwise move on to next sequence.
 4. Save the result for further processing unless there are already N_i better matching sequences saved. Save the results in order of significance, keeping the best N_i thus far. Move on to next sequence.
- D. For each entry in the list saved in step C4 above:
 1. Perform a gapped alignment with traceback (i.e., collect score, extent, position of indels, etc.) using an X_{fg} that is larger than X_g . The larger X_{fg} means that the score and ranking of a match may change. If CBS, then also adjust the score and expect value based on the composition of the subject sequence (the composition of the query is always considered). This may change the score and ranking of a match, sometimes dramatically.
 2. Add the resulting match to a new ordered list. A tie (two matches with identical score and expect value) is broken by the order of the sequences in the database. Almost every entry processed in the last step results in a significant match, but an alignment calculated with CBS may become much less statistically significant and will no longer be saved.
- E. Format a report based on the list saved in D2:
 1. Discard the $N_i - N$ least significant matches.
 2. Print results for the first N matches.

The retention of $N_i > N$ matches through the internals of BLAST is intended to ensure that if some matches become more or less significant, in the last phase of constructing the alignment, that BLAST will still show the user the most relevant matches. For CBS, we increase N_i by a larger amount than for standard gapped BLAST, as the application of CBS may result in a larger change in the significance of a match. For the same reason, the internal expect value is also increased from the user requested value if CBS is requested.
